Results: VAT (g) was comparable between patients and controls [median (25th – 75th percentile) 64 (23-149) vs 66 (30-99), p=0.98] and between patients with oligo disease and poly disease [46 (22-123) vs 80 (23-167), p=0.32]. Patients presented lower serum levels of APOA1 and RBP4, and elevated serum levels of IL-6, progranulin and MCP-1 (Table 1) as compared to the controls. Patients with poly disease had lower plasma levels of LDL-C, LILA, IL-1RA, progranulin and VEGF, and elevated serum levels of IL-1b and IL-1b/IL-1RA ratio (Table 1) as compared to patients with oligo disease. No statistically significant differences were seen between neither patients and controls nor patients with oligo disease and poly disease for TC, HDL-C, APOB, CRP, leptin, adiponectin, NGAL, angpl1, angopoietin, chemerin and resistin. In patients, higher IL-6 [unstandardized B (95% CI)] 48.7 (25.1, 72.2), p<0.001, resistin [8.5 (5.1, 11.6), p<0.001] and leptin [2.5 (0.9, 4.0), p=0.002] were identified as correlates for higher VAT. In controls, only higher leptin [unstandardized B (95% CI)] 5.3 (3.7, 6.9), p<0.001 was identified as correlate for higher VAT.

Conclusion: Despite similar mass, VAT seems to be closely related to IL-6 and resistin suggesting an active metabolic role in JIA. In addition to IL-6, several pro-inflammatory adipokines/cytokines were increased in JIA potentially playing a role in disease activity. Novel biomarkers, among them IL-1b/IL-1RA, were identified for differentiating between oligo vs poly disease.

Background: The term juvenile idiopathic arthritis (JIA) represents a heterogeneous group of disorders, all manifesting joint inflammation, but with different clinical phenotypes, disease course, and outcomes [1, 2]. In Argentina, information about patients with JIA is scarce. In our country, different factors such as the diversity of sociodemographic conditions and the disparities in the access to health care, could influence the JIA subtypes prevalence and prognosis of these patients.

Objectives: To describe the sociodemographic and clinical characteristics of patients with different subtypes of JIA.

Methods: Descriptive, retrospective, chart review and multicenter study. Patients were included with a diagnosis of JIA, according to ILAR criteria (2001) and onset of symptoms ≤ 16 years, diagnosis within the last 3 years and with at least 12 months of follow-up since diagnosis by the same physician or treating team. Sociodemographic variables, clinical variables prior to diagnosis by the pediatric rheumatologist, time to specialist consultation, treatments prior to diagnosis and variables at the time of diagnosis by the specialist were recorded. Data was analyzed using SPSS 25.

Results: 320 patients from 17 specialized care centers in Argentina (11 public and 6 private) were included. The mean age at symptom onset was 6.9 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients had private medical insurance and 67.8% public. The mean education (in years) of the parents was 13.6 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients had private medical insurance and 67.8% public. The mean education (in years) of the parents was 13.6 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients had private medical insurance and 67.8% public. The mean education (in years) of the parents was 13.6 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients had private medical insurance and 67.8% public. The mean education (in years) of the parents was 13.6 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients had private medical insurance and 67.8% public. The mean education (in years) of the parents was 13.6 years (SD 4.09) and 65.6% of the patients were girls.

Conclusion: This is the first national multicenter study of patients with JIA, and the first national multicenter study of patients with JIA in Argentina. The study cohort included 39 patients; general features of the cohort are reported in Table 1. The median age at the first bDMARD was 5.9 years (interquartile range [IQR] 5.3) years. The prescription pattern of bDMARD is shown in Figure 1. Etofenac and adalimumab were the most frequently prescribed bDMARD (16 and 15 times, respectively). The causes of the first bDMARD discontinuation were the following: articular flare (43%), uveitis (33%), both articular and uveitis flare (6%), and adverse treatment effects (20%). Discontinuation of the first bDMARD due to articular flare was significantly more frequent in patients treated with adalimumab than with etanercept (73% vs. 25%; p=0.01). Conversely, the rate of bDMARD withdrawal due to active uveitis was higher in etanercept-treated patients than in adalimumab ones (38% vs. 20%; p=0.04). The discontinuation rate due to uveitis was significantly higher in the infliximab group than in the adalimumab group (80% vs. 20%; p=0.03). The median age at the second bDMARD was 9.4 years (IQR 7.3) years. The majority of the cohort (80%) received a TNFi as the second bDMARD. Adalimumab was the most prescribed second bDMARD (55%) followed by infliximab (29%); the most frequent switch was from etanercept to adalimumab (13 times) (Figure 1). To note, the concomitant use of MTX decreased significantly between the two bDMARDs courses (85% vs. 64%; p = 0.04). The rate of clinical inactive disease (CID) at 3, 6, and 12 months did not differ significantly between the first and the second bDMARD. The general CID (defined as the ever achievement of CID) rate was lower during the first bDMARD course compared to the second (79% vs. 95%; p=0.04). A non-TNFi was prescribed as the second bDMARD in 8 patients (20%); 4 subjects received abatacept (2 for articular disease and 2 for adverse effects), and 4 subjects were treated with tocilizumab (all for articular disease). Uveitis activity represented the main reason for discontinuation in almost half of the patients who switched to a TNFi as the second bDMARD. No significant differences in sociodemographic conditions were observed during the second course of bDMARDs between patients treated with TNFi or non-TNFi. Eighteen patients discontinued the second bDMARD: 16/31 (52%) from the TNFi group and 2/8 (25%) from the non-TNFi group. The reasons for discontinuation were articular flare (60%), uveitis flare (22%), both articular and uveitis flare (6%), and adverse events (12%).

Conclusion: Most of the patients in our cohort received a TNFi as the second bDMARD, with a significant proportion of patients being treated without MTX. No...
apparent differences were seen between the non-TNFi and TNFi for the achievement of clinical inactivity disease. Larger studies are needed to explore the choice of the second bDMARD in JIA.

**CESAREAN SECTION IN WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS – A POPULATION-BASED STUDY**

**Keywords:** Quality of care, Pregnancy and reproduction, Registries

**C. Sieper,1,2 S. Lydersen,3 K. A. Salvesen,4 M. Wallenius,5 Norwegian University of Science and Technology, Department of neuromedicine, and movement science (INB), Trondheim, Norway; 2 Ålesund Hospital, Rheumatology, ÅLESUND, Norway; 3 Norwegian University of Science and Technology, Regional Centre for child and youth mental health and child welfare, Trondheim, Norway; 4 Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine (IKOM), Trondheim, Norway

**Background:** The literature on delivery methods in women with juvenile idiopathic arthritis (JIA) is insufficient. Active inflammation is a risk factor for cesarean section (CS) in other arthritic diseases. A CS entails a higher risk for complications than vaginal delivery and a restricted physical activity the first weeks after birth.

**Objectives:** To explore a possible association of inflammatory active disease and the proportion of CS in women with JIA.

**Methods:** Data from the Norwegian nationwide observational register RevNatus were linked with data from the Medical Birth Registry of Norway (MBRN). Cases comprised singleton births in women with JIA (n=196) included in RevNatus 2010 to 2019. Singleton births registered in MBRN during the same period of time and excluding mothers with rheumatologic inflammatory diseases (n=575,798) served as population controls. Disease activity was assessed using Disease Activity Score with CRP (DAS28-CRP-3). We defined inactive JIA as DAS28-CRP-3 ≤2.6 and active JIA as DAS28-CRP-3 ≥2.6.

**Results:** CS was more frequent in women with JIA (20%) than in population controls (15.6%) and occurred most frequently in inflammatory active JIA (30.0%). Women with JIA had similar risk for elective CS (risk difference 1.1%, 95% CI 1.7 to 5.4) and higher risk for emergency CS (risk difference 3.8%, 95% CI -0.4 to 9.3) compared with population controls. Active disease increased the risk for emergency CS (risk difference 14.0%, 95% CI 4.3 to 27.4).

**Conclusion:** Women with active JIA had higher risk for emergency CS compared with population controls.

**ASSESSMENT OF SCHOOL OUTCOMES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

**Keywords:** Education, Patient reported outcomes, Inflammatory arthritides

M. Ghaï1, D. Khalifa1, M. Cheour1, R. Fakhtakh1, N. El Amri1, K. Baccouch1, E. Bouajina1, 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

**Background:** Juvenile idiopathic arthritis (JIA) is the most common inflammatory arthropathy in childhood. It can often be disabling, have an impact on the child’s integration, and affect school attention to varying degrees.

**Objectives:** The objective of this study was to assess the impact of juvenile idiopathic arthritis (JIA) on children’s educational outcomes.

**Methods:** This is a cross-sectional monocentric study including school-age children with JIA diagnosed according to the International League of Associations of Rheumatology (ILAR) classification criteria. Data were collected for all children on their school level, school difficulties, attendance, and absenteeism. Academic failure was defined by either dropping out of school or grade retention.

To evaluate disease activity we used the Disease activity score (DAS-28) for oligoarticular and polyarticular forms, and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score for axial forms. The Childhood Health Assessment Questionnaire (C-HAQ) was used to assess functional disability.

**Results:** Thirty-six patients were enrolled. The average age was 13.5 ± 5.9 with a female percentage of 55.6%. The polyarticular form was the most frequent (52.8%) meanly seronegative, followed by the Oligoarticular form (13.9%), then the enthesitis-related form (12.4%). None of our patients was illiterate. Eight children (22.2%) dropped out of school because of their functional disability. Students with JIA who attended school had an absenteeism rate of 67.8%. Slightly more than half of the JIA patients (57.1%) failed at least one grade. Academic failure was associated with a high disease activity (p<0.003), the presence of joint deformities (p=0.002), a high C-HAQ score (p=0.01), and an erythrocyte sedimentation rate: ESR ≥100 mm/h (p=0.02). The absenteeism rate was associated with rural origin (p=0.004), pain level (p=0.02), high disease activity (p=0.01), hip involvement (p=0.001), and a high C-HAQ score (p=0.03).

**Conclusion:** Our study shows that the schooling of children with JIA was negatively influenced by this disease. Proper control of the disease activity and inflammation will guarantee better school attendance and increase academic performance.

DOI: 10.1136/annrheumdis-2023-eular.5972
Background: Juvenile Idiopathic Arthritis (JIA) is an umbrella term for chronic arthritis with onset before 16 years of age. According to ILAR classification criteria, it is subdivided in 6 category. Growth failure is a well observed phenomenon in JIA and more so in Systemic onset and polyarticular variants. Except from western literature, in Asian countries Enthesitis Related arthritis (ERA) is more prevalent. In our study, we have studied the growth and development of patients with Enthesitis Related arthritis variant.

Objectives: To assess the prevalence of growth failure and sexual maturity in patients with JIA-ERA and possible association with disease activity, damage and drug therapy.

Methods: We have enrolled all patients of JIA-ERA, visiting rheumatology out-door patient service in KGMU, Lucknow, from July 2021 to Dec 2021. All the patients must qualify Revised ILAR classification criteria for ERA. Those who have concomitant developmental disorders, secondary amyloidosis and macropathic activation syndrome were excluded from the study. All patients were clinically examined and previous medical records were thoroughly checked. Anthropometric measure and Tanner staging was done at baseline. Growth velocity was observed at follow up visit. This is a Prospective observational study with follow up at 3 and 6 months.

Results: 50 patients of JIA-ERA were enrolled. Majority of them were boys with a male to female ratio of 4.5:1 and mean age of 15.5 years. Mean age of onset was 11.5 years with a mean disease duration of 41.25 months. 32% had family history of SpA in first degree relatives and 12% had history of uveitis in parents. Only 3 patients (6%) had history of other autoimmune diseases in family. There was no developmental delays in children with JIA-ERA and 47 patients (94%) were underweight for their age with low BMI. 30% patients had mid parental height. 12 patients (24%) had significant limb length discrepancy. 64% were underweight for their age with low BMI. 30% patients had achieved age appropriate linear growth with 20% were 2SD above their mid parental height. 12 patients (24%) had significant limb length discrepancy. 64% were underweight for their age with low BMI. 30% patients had mid parental height. 12 patients (24%) had significant limb length discrepancy.

Conclusion: Growth failure wasn’t well observed in JIA-ERA variants. One third had delayed sexual maturity for their age. Growth velocity was similar to age matched healthy population. No significant association was found with prior corticosteroid use, disease duration, disease activity (JSPADA and JADAS27) and damage (JADIS) score.

POSO778 ADALIMUMAB AND ANTI-DRUG ANTIBODIES IN A COHORT OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A SINGLE-CENTER EXPERIENCE

Keywords: Inflammatory arthropathies, Targeted synthetic drugs, Outcome measures

G. Tarantina1, D. Pires Marafon1, F. Comitini2, R. Simeoli3, A. Aquilani4, R. Nicolai1, E. Marasco1, F. De Benedetti1, S. Magni-Manzoni1.

Background: Adalimumab (ADA), a fully humanized antibody against tumor necrosis factor (TNF)-α, has revolutionized treatment of patients with juvenile idiopathic arthritis (JIA). Although most of these respond within the first weeks, a minority may show loss of response (LOR) after continued exposure. Many studies demonstrate the influence of anti-adalimumab antibodies (AAA) and drug concentrations and clinical outcome in adults. However, little information about AAA and LOR is available for children with JIA.

Objectives: To describe demographic and clinical features in a single-center cohort of JIA patients treated with ADA, grouped according to frequency of drug administration (1W vs 2W); to assess ADA levels versus AAA titers and, finally, to investigate possible correlation between LOR to ADA and AAA.

Methods: Records of JIA patients on ADA treatment were retrospectively reviewed with focus on medical history and ELISA (enzyme-linked immunosorbent assay) ADA/AAA levels in a 12-month-period (Feb 2021-Feb 2022). Children with idiopathic uveitis were excluded. Samples furthest from last drug administration was defined as “trough level.” Data were analyzed via descriptive statistics (STATA 15.1).

Results: Of 61 JIA patients treated with ADA (49% females), 38 had AAA positive oligoarthritis with almost one large joint involvement at disease onset (T0). None of them presented RF-positive polyarthritis, nor systemic JIA (s-JIA). The median age at T0 was about 3 years. Half of study cohort was b-DMARDs naive at ADA start (T1), while all children were on c-DMARDs. Chronic recurrent uveitis was the main reason for ADA starting, followed by tenosynovitis and spine or hip active arthritis. At the first ADA/AAA sampling (T2), approximately 15% of patients had active disease, with elbows or wrists as the most frequently involved. Extreme variability was observed between AAA titers (median 7.4 AU/ml and ADA levels (median 15.4 micrograms/ml), regardless from 1 or 2-weekly administration. ADA levels, compared to the doses from last drug administration, reached plateau values corresponding to a pharmacokinetic steady state. Among these in only 6 we found very high AAA titers (350.0 - 113.4 AU/mL). In the subgroup of 37 patients with “trough-level” sampling heterogeneous data about AAA titers and ADA levels were observed.

Conclusion: Our preliminary data showed a possible association between occurrence of AAA and lower ADA levels. However, a targeted risk analysis about high AAA titers and LOR incidence was not available. Monitoring of drug immunogenicity should be implemented in daily practice and become subject of future studies JIA.

Clinical cases

POSO778 METASTATIC ANGIOSARCOMA MASQUERING AS SYSTEMIC INFLAMMATORY DISEASE WITH REFRACTORY PERICARDITIS

Keywords: Malignancy, Heart

K. Williamson1, Mayo Clinic, Rheumatology, Rochester, United States of America

Background: Rheumatologists are frequently asked to evaluate patients with acute pericarditis. The majority of cases are idiopathic with systemic autoimmune disease underlying maybe 7% or less of cases in developed countries.[1-2] It is critical to recognize the presence of systemic symptoms or poor prognostic pericarditis features, such as tamponade physiology or poor response to non-steroidal anti-inflammatory drugs, that raise concern for a malignant etiology of pericarditis.[1-2]

Objectives: A case report of a patient presenting with refractory pericarditis caused by metastatic angiosarcoma.

Methods: A 46 year old male presented for evaluation of unresolving pericarditis. Five months prior, he had developed abrupt-onset pericarditic chest pain with associated dyspnea. Initial ED evaluation was notable for normal troponins and non-specific T wave abnormality on ECG. CT chest angiogram revealed a trace pericardial effusion and isolated right axillary lymphadenopathy. The patient declined further evaluation. He presented a week later with persistent pericarditic pain. Echocardiogram showed enlargement of the pericardial effusion with possible early tamponade. Respiratory viral testing was negative. C-reactive protein (CRP) was elevated to 20.83mg/dL (Ref ≤0.5mg/dL) and ferritin to 2344.4ng/
mL (Ref 2.18-274.7ng/mL). Soluble IL-2 receptor and blood counts were normal. Rheumatoid factor was weakly positive with ANA, anti-DNA, anti-CCP, and ANCA returning negative. Core needle biopsy of an auxiliary lymph node was negative for malignancy. Percarditocentisis was deferred due to patient preference and stability. He was started on colchicine for autoimmune versus idiopathic pericarditis without significant improvement. He was transitioned to prednison due to improving in his chest pain, effusion, and CRP: dyspnea and hyperferritinemation persisted. Attempts to taper prednison failed due to flaring of pericarditis. The patient was referred to our center for evaluation of refractory pericarditis and possible systemic inflammatory disease. No signs or symptoms of RA or CTD were present. The patient endorsed recent night sweats, 11 kg of weight loss, and new bone pain. Full body PET/CT was pursued and demonstrated two FDG avid masses adjacent to the right side of the heart along with multiple lytic bone lesions of the spine and pelvis.

Figure 1. (A) PET Maximum intensity projection showing large cardiac mass (red arrow) and multiple FDG avid bone lesions (yellow arrows). (B) PET Axial fused image showing large FDG avid cardiac mass.

Results: Cardiac CT confirmed malignant-appearing, centrally necrotic mass along the right side of the heart extending to involve the pericardium. Iliac bone biopsy confirmed a diagnosis of metastatic angiosarcoma. He was not a candidate for cardiac tumor resection and was referred to oncology for palliative chemotherapy.

Conclusion: Primary malignant cardiac tumors are a rare cause of pericarditis. Cardiac angiosarcomas are the most common type of primary malignant cardiac tumor. They most commonly arise from the right atrium or pericardium and may present with pericarditis-like symptoms.[3]

BRAIN TUMOR-LIKE LESIONS AS FORM OF PRESENTATION OF NEUROPSYCHIATRIC LUPUS

Keywords: Systemic lupus erythematosus, Imaging

I. L. Mamani Velarde1, I. Altabás González1, C. Mourinho Rodrigues2, S. García Pérez1, I. Hernández2, J. M. Pego-Reigosa1. 1IRIDIS Group (Investigation in Rheumatology and Immune-Diseases), Galicia Sur Health Research Institute (ISGS), Department of Rheumatology, University Hospital of Vigo, Vigo, Spain; 2University Hospital of Vigo, Department of Rheumatology, Vigo, Spain

Background: Neuropsychiatric (NP) systemic lupus erythematosus (SLE) encompasses a broad spectrum of syndromes.[1] The attribution of the NP manifestations to the disease itself is a challenge and is critical to selecting the correct treatment. [2]

Objectives: To present a case of a woman with SLE who developed brain tumor-like lesions.

Methods: The clinical manifestations, complementary tests, treatment are described.

Results: 28-year-old woman with a history of SLE with moderate disease (constitutional, cutaneous, musculoskeletal, hematologic and serological) and frequent flares despite treatment with hydroxychloroquine and doses of prednisone up to 20mg/day. She was admitted to the rheumatology service due to a severe flare-up of SLE, with headache, fever, worsening of lesions in photo-exposed areas, lymphadenopathy, arthralgia, nausea, and vomiting. Blood tests showed platelets 60,000/μL, elevated ESR, abnormal liver biochemical, decreased C3, normal urine, with no data of infectious etiology. After treatment with iv methylprednisolone (250mg x 3) and iv belimumab (600mg), she presented clinical and analytical improvement and was discharged from the hospital. Three days later, the patient presented persistent headache and fever, and decreased level of consciousness; laboratory tests showed leukocytosis, anemia, abnormal liver function tests, elevated ESR and CRP. She was referred to the emergency room. On the neurological exam: patient disoriented in time and space, opened her eyes only after painful stimulus, signs of dysarthria, and facial paralysis. CT scan revealed a space-occupying lesion (3 x 2cm), at the level of the right basal nuclei with perilesional edema and collapse of the anterior horn of the right lateral ventricle, discreet mass effect with displacement midline, and similar contralateral involvement. The patient was admitted to the hospital due to a probable primary neoplasm of the central nervous system, without being able to initially exclude infectious, vascular, and inflammatory pathologies. Treatment was started with iv dexamethasone and empiric therapy for bacteria, viruses, fungi, and parasites. The following day, brain MRI (Figure 1, A - B) showed lesions in the right and left basal ganglia, with a mass effect in the right basal ganglia and images of their interior with artifact related to hemosiderin or deoxyhemoglobin, related to history of bleeding from the lesions. Alteration of thickness and irregular subependymal signal in the occipital horns. The stereotaxic brain biopsy showed parenchyma with intense acute inflammatory changes, with necrosis and vascular inflammation, without histopathological features of etiological specificity, and no evidence of neoplasia. The lumbar puncture did not show alterations, cytology without malignant cells, antibodies against onconeuronal proteins negative. Ruled out infectious etiology. Slow progressive improvement in clinical and laboratory manifestations and in imaging tests improvement was seen in response to the therapy with high doses of glucocorticoids and cyclophosphamide pulses. After prolonged hospitalization, she was discharged from the hospital, her neurologic status being normal. Brain MRI (Figure 1, C-D), two months after discharge, showed a clear decrease in the size of the brain lesions.

Conclusion: To the best of our knowledge, no brain space-occupying lesions (simulating neoplasms) attributed to SLE have been described. The context of concomitant activity, the negative results for infectious/malignant diseases, and the favorable response to immunosuppressive treatment, support the neuroinflammatory etiology.

Figure 1.
Positioning of the temporomandibular joint: a case report

**Keywords:** Pain, Ultrasound, Crystal arthritis

B. Maranini1, S. Mandrioli2, M. Galiè2, M. Govoni1, 1University of Ferrara, Department of Medical Sciences, Ferrara, Italy; 2University of Ferrara, Department of Cranio-Maxillofacial Surgery, Ferrara, Italy

**Background:** Deposition of calcium pyrophosphate dihydrate crystals occurs in crystalline arthropathies, such as gout and chondrocalcinosis. Occasionally, crystal deposits may affect the temporomandibular joint (TMJ), especially involving the articular cartilage and fibrocartilage, causing pain and jaw claudication, mimicking giant cell arteritis (GCA). Ultrasound (US) images reveal spotted hyperechoic signals in the articular disk and sometimes a marked destruction of the condyle with erosive changes.

**Objectives:** To highlight and discuss the potential role of TMJ US in guiding differential diagnosis of orofacial pain syndrome (frontal headache and jaw claudication), arousing the suspicion of GCA.

**Methods:** Case-report describing an old patient presenting with severe headache and jaw claudication with particular reference to the role of TMJ US in differential diagnosis of an initially suspected GCA.

**Results:** An 85-year-old woman presented to the Emergency Department with a 2-days history of progressively worsening frontal headache and jaw claudication. She reported no visual loss or polymyalgia rheumatica symptoms. Right temporal artery tenderness was appreciated on clinical examination, without reduced temporal arterial pulse. No axillary, brachial, or carotid bruits were appreciated. Neurologic examination was normal; brain computed tomography (CT) revealed no intracerebral hemorrhage or intraparenchymal lesions. Her erythrocyte sedimentation rate was 67 mm per hour, and C-reactive protein level 3.30 mg per deciliter. Temporal artery US revealed no abnormalities (absence of halo sign or arterial stenosis). Since patient complained of chewing pain and given that temporomandibular disorders may be misdiagnosed as GCA, TMJ US was performed revealing the presence of extensive calcifications around the right temporomandibular head and in the meniscus (Figure 1, Panel A). Brain CT images were then carefully reviewed: in the right TMJ massive calcifications surrounding the right temporomandibular head were appreciable (Figure 1, Panel B). Moreover, coronal CT scan of the atlantoaxial region showed calcifications of the alar ligaments, particularly evident on the superior-left side (Figure 1, Panel C). High dose glucocorticoid regimen was then started (Methylprednisolone 40 mg once daily). The patient's pain rapidly improved, steroid was rapidly tapered until withdrawal, with a complete resolution of symptoms within few weeks.

**Conclusion:** Crowned dens syndrome is characterized by recurrent neck pain related to radiodense deposits of hydroxyapatite or calcium pyrophosphate dihydrate in ligaments around the odontoid process, which create the appearance of a crown or halo surrounding the odontoid process on radiographic imaging. Evidence of inflammation (e.g., fever or elevated levels of C-reactive protein) is usually observed. A short course of steroids, followed by administration of non-steroidal anti-inflammatory medication, usually completely alleviates symptoms. Rarely, temporal arteritis headache may mimic TMJ irradiation pain, or present as jaw claudication. In this case, temporal arteries and TMJ US can enable to discern a halo sign, as a hallmark of giant cell arteritis, from suspicious signs of TMJ disorder. Rapid diagnosis can prevent misdiagnosis, invasive and unnecessary investigations (temporal artery biopsy) and inappropriate treatment (long term steroid regimen, leading to cardiovascular risk and increased bone loss).

Arthritis research

**Keywords:** COVID, Best practices, Vitamin D

B. Nieradko-Iwanicka1, 1Medical University of Lublin, Department of Hygiene and Epidemiology, Lublin, Poland

**Background:** Before the COVID-19 pandemic it was estimated that nearly 70% of the population is deficient in vitamin D - 25(OH)D <20ng/ml in Poland [1]. The percentage was expected to increase due to indoor isolation during the COVID-19 pandemic. Vitamin D has a positive effect on the condition of the bones, affects the course of autoimmune diseases, the course of neurological diseases, in type 2 diabetes, vitamin D supplementation improves glucose tolerance and reduces insulin resistance [2,3,4].

**Objectives:** The aim of the retrospective study was to determine what percentage of rheumatology clinic patients suffer from vitamin D deficiency and whether this condition is effectively treated.

**Methods:** In January 2023, a retrospective analysis of the documentation of 172 patients treated at the Rheumatology Outpatient Clinic in Bełżyce (Poland) in 2022 was conducted.

**Results:** The mean age of the 172 patients whose documentation was analyzed was 60.43 years (min 19, max 88). There were 132 women (76.8%) and 40 men (23.2%) in this group. The mean concentration of vitamin D was 25.57ng/ml±SD11.9 (min 5.7, max 75, Me 22.8). Vitamin D deficiency was found in 44% (serum concentration <20ng/ml), suboptimal concentration (20-30ng/ml) in 31%, optimal concentration (30-50ng/ml) in 21%, and high concentration (>50ng/ml) in 4%. All those with a deficit or deficiency (75 people) were prescribed cholecalciferol in a dose of 20,000 units orally. 1 capsule twice a week after breakfast for 2 months [5]. Patients with optimal vitamin D levels were advised to take a dose of 2,000 units per day. Among the patients with deficit or deficiency, 48 people came for a follow-up visit to check the level of vitamin D (64% of the group with too low vitamin D concentration; 28% of the entire group whose documentation was analyzed). In the follow-up examination, the mean concentration of vitamin D was 37.14±9.8ng/ml (min 28, max 84, Me 35.3). Therefore, a statistically significant increase in the concentration of vitamin D in the blood was noted (p<0.05). In the group of people who came for the follow-up examination, there were 35 women, whose mean age was 60.7 years and 13 men (mean age 68.2 years).

**REFERENCES:**

Conclusion: 1. During the COVID-19 pandemic in the group of outpatient rheumatology patients, 75% had a deficiency or suboptimal level of vitamin D. 2. Treatment with cholecalciferol in a dose of 20,000 IU twice a week orally for 2 months is effective treatment of vitamin D deficiency. 3. Too low percentage of patients diagnosed with vitamin D deficiency come for visits and check-ups.

POS0782-PARE MANAGING PSORIATIC ARTHRITIS: PATIENTS’ VIEWS AND ATTITUDES TO USING AN ONLINE WELLNESS PROGRAM

Keywords: Psoriatic arthritis

W. B. Nowell1, A. Degrassi1, S. Venkatachalam1, K. Gavigan1, A. Krivohlavek1, E. Rivera2, M. E. Husni2.

Background: Patients diagnosed with psoriatic arthritis (PsA) confront decisions about how to optimize treatment of their chronic disease including patient physician interaction and modifying their own lifestyle choices that may impact their disease outcomes.

Objectives: To examine PsA patients’ views and attitudes of managing their disease using a guided online wellness program to address lifestyle behaviors such as nutrition, exercise, sleep, and stress management.

Methods: A cross-sectional online survey was developed with patient and clinician input and administered to US adults with a self-reported diagnosis of PsA in the ArthritisPower registry. Survey questions assessed participant (pt) experience with, and motivations to participate in, an online wellness program through various mechanisms to address nutrition, exercise, sleep and stress management. E-coaching is a validated tool using email coaching as an individualized tailored communication on wellness strategies to improve lifestyle behaviors.

Results: 312 pts completed the survey, of whom 83.0% were female, 91.0% white, mean age 57.1 (SD 11.4) years, and 10.0 (SD 10.2) years since PsA diagnosis. Most pts (93.6%) were diagnosed by a rheumatologist for their PsA. Over 90% of pts reported being ‘somewhat likely’ or ‘very likely’ to interact with an online coach at least twice a week or spend one to two hours a week learning about nutrition, exercise, sleep and stress management (90.4% and 92.6%, respectively) if they had the opportunity to take part in a wellness program. However, only 8.7% of pts are currently participating in a structured wellness program. Feeling better was the top motivator for participating in a wellness program (179, 57.4%) followed by the want to improve PsA symptoms (145, 46.5%). About a third of pts would prefer to participate in a wellness program by interacting with an online trained professional (34.0%), followed by attending an online course (16.4%) and reading written material (16.0%) (Table 1). In reporting barriers to wellness changes, cost and not having the energy to make changes were selected by about half of pts (both 47.1%) (Figure 1). Over one-tenth (13.1%) of pts reported having no barriers to participation in wellness programs.

Conclusion: The overwhelming majority of patients report willingness to be involved in a wellness program. Feeling better is a top motivator, while cost and lack of energy to make changes were top barriers to adopting wellness behaviors.

Our study results support the use of guided online participation in wellness programs over alternatives such as online courses and written materials. Further studies are needed to elucidate how e-coaching wellness platforms may improve and sustain lifestyle changes in PsA patients.

POS0783-PARE WITHDRAWN
Keywords: Self-management, Safety, Patient reported outcomes

T. Woodworth1, M. C. Hay1, A. Leong1, D. Furst1. 1University of California, Los Angeles, David Geffen School of Medicine, Division of Rheumatology, Los Angeles, United States of America

Objectives: To explore whether rheumatoid arthritis (RA) patients' concerns regarding adverse events (AEs) during their treatment are adequately collected and considered in making treatment decisions.

Methods: Using pilot focus groups, and after obtaining voluntarily 12 RA patients (8 women, 4 men, duration RA 1 to > 20 years) met in groups of 4 and described their concerns regarding how they experience being treated for RA. All patients were from Southern California and spoke and understood English fluently. We recorded/transcribed three 90-120 minute focus groups. Participants completed an 18 item Beliefs about Medications Questionnaire (BMQ), which included 10 specific arthritis medication questions and 8 questions about doctors. They examined a table describing 75 AEs of concern to oncology patients - the PRO-CTCAE (Patient Reported Outcome-Common Terminology for Adverse Events), and checked AEs they had experienced or were of concern. Data were recorded and transcribed from all 90-120 minute sessions. Using Dedoose software, transcriptions were inductively coded and analyzed to identify specific areas of associations with RA medications. A total of 225 excerpts were extracted to which a total of 607 codes were applied.

Results: AEs associated with medications were the explicit objective of this study and so we could not estimate the percent of patients with medication-related AE concerns. Of the 36 excerpts in which participants discussed AEs while discussing particular types of medications, conventional synthetic DMARD (csDMARD) were more likely to be discussed than biologics/ targeted synthetic DMARD (b/tsDMARD) (58% csDMARDs, 28% b/tsDMARDs, 14% corticosteroids). 42 unprompted comments emphasized self-management strategies. 10/42 specified the context of medications, such as modifying dosages (40%) or stopping medication altogether (60%); of these, 8/10 comments specified csDMARDs or corticosteroids. Four of 12 voiced uncertainty about whether AEs were related to RA, medications, or something else. On the BMQ, participants generally agreed that their health depended on their medications, which protected them from becoming worse and that the medicines did more good than harm. Nevertheless, their medications disrupted their lives, and they worried about long-term effects. Generally, participants did not think doctors used too many medications or placed too much trust in the medications. In each focus group, participants found the PRO-CTCAE bewildering and raised the specter of cancer due to their medications. The 10 most commonly marked AEs were dry mouth, mouth sores, nausea, bloating, diarrhea, abdominal pain, hair loss, bruising, general pain and fatigue.

Conclusion: Medications were generally viewed positively but AE concerns were more common among those using csDMARD than b/tsDMARDs or corticosteroids. Concerns about AEs triggered self-management strategies, potentially affecting adherence. We suggest that a robust mechanism for patients to explicitly report the impact of AEs that they are experiencing could facilitate clinical communication and positively impact adherence.

DOI: 10.1136/annrheumdis-2023-eular.6393
Background: To be diagnosed with inflammatory arthritis (IA) is challenging for the individual, who may experience uncertainty and anxiety [1,2]. We need more knowledge on how health professionals can support patients that have been diagnosed recently. Previous studies have focused on patients’ experience of living with IA, but few have aimed to focus on the newly diagnosed.

Objectives: This study aimed to explore patients’ experiences, thoughts, and concerns after being diagnosed with IA.

Methods: Participants were patients newly diagnosed with IA (rheumatoid arthritis or psoriatic arthritis) recruited through a feasibility study to a self-management intervention [3]. Data was collected through semi-structured interviews. The analysis was based on reflexive thematic analysis method, which provides a rich and complex understanding of patterns within data [4].

Results: Twelve adults (six men and six women, aged 25-77) diagnosed with rheumatoid arthritis (n=8) or with psoriatic arthritis (n=4) within the last three months, were interviewed at an outpatient rheumatology clinic in Denmark. We identified four main themes: 1) The intrusiveness of arthritis. Symptoms affected patients physical and emotional state. The initial symptoms were experienced very differently. For some, symptoms were acute and explosive. In others, disease progression was slow, and participants became more and more invalidated with time. However, all experienced that arthritis affected their mood, and in general, patients were overwhelmed to being diagnosed with arthritis. 2) Getting familiar with arthritis and its treatment. Patients requested information about how to manage IA, and several were already seeking information about non-pharmacological treatments such as different diets, meditation, and exercises. The participants paid great attention to how they responded to the pharmacological treatment and how their bodies reacted in different situations. Furthermore, the newly diagnosed also strove to become acquainted with their new body with arthritis. 3) Adapting to life with arthritis. Some felt it natural to tell family members about their arthritis. In contrast, others thought it was none of their concern and did not like to bother them. The participants did not want arthritis to be an issue for other people to worry about. 4) Worries about the future. Overall, the pharmacological treatment had a profound focus immediately after diagnosis. Worrying about the potential lack of effect contributed to great concern and frustration. The worries were related to all aspects of life, including work and family life. However, the newly diagnosed also hoped that symptoms would be acceptable so that everyday life could be restored. Nevertheless, they also realized that they had to rethink how they wanted to prioritize in the future.

Conclusion: The results of this study highlight the complexity of being newly diagnosed with IA. Time after diagnosis is dominated by worries about the benefit and harms of pharmacological treatment and the future. However, the participants did not want to perceive themselves as being sick. Instead, they strove to comfort themselves with hope for successful pharmacological treatment together with taking their own non-pharmacological initiatives.

POS0786-PARE

CONNECTING THROUGH SHARING - PUBLISHING A BOOK FOR YOUNG PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES (RMDs) BY YOUNG PEOPLE WITH RMDs

Keywords: Quality of life, Mental health, Self-management

Background: Research has shown that adolescents with chronic conditions such as rheumatic and musculoskeletal diseases (RMDs) are more prone to developing psychiatric conditions. Reasons for this could be the common stigmatization that they encounter in their daily life and the feeling of being the only odd one out. Youth-R-Well.com, the Dutch organization for youth (18-30 years) with RMDs, responded to this by providing monthly columns from their peers with RMDs. These columns show the daily life and struggles of young arthritis patients with a touch of humor, thus providing some of the much needed recognition.

Objectives: The main objective of this project is to provide information, recognition and awareness about the daily life and struggles of young RMD patients. By reading the columns that were written lightly humorously, it will be easier for young people to find the much needed recognition that they often lack in their own environment. These columns do not only recognize the often experienced pain and (chronic) fatigue, but also recognize the insecurities that come with living with a RMD, and show ways to face them. By describing their daily life, these young people provide tips on how to approach certain situations. Therefore, besides providing information and recognition, these columns can also function as a tool that increases the self-management of their disease.

Methods: To provide these columns, different young people with a RMD (18-30 years) were asked over the years to regularly write columns that were published on the website of Youth-R-Well.com. To draw more attention to the columns and reach more people, e.g., by distributing the books in hospitals, the columns of one of the writers will be published in a book.

Results: Since 2012, approximately 150 columns have been published on the website of Youth-R-Well.com, from nine different writers. Youth-R-Well.com has received, and still receives, many thankful messages from young people with RMDs, saying that they benefited a lot from the tips and recognition that the columns provided. The book has not been published yet, but Youth-R-Well.com is right now talking to self-publishing companies, and has also received commitments from parties that will take partial responsibility for the costs of publishing.

Conclusion: Publishing columns on a regular basis has helped a lot of young RMD patients in the Netherlands to feel recognized in their struggles with living with a RMD. They have said to have learned a lot about how to cope with certain issues that come with having a RMD. This is something Youth-R-Well.com will definitely continue with. The book is unfortunately not published yet, but will be in the near future.

**PHYSICAL ACTIVITY GUIDANCE IN THE RHEUMATOLOGY CLINIC – PATIENT EXPERIENCES AND PREFERENCES. A QUALITATIVE STUDY**

**Keywords:** Qualitative research methods, Lifestyles, Rheumatoid arthritis

**T. Thomsen**1,2, M. Aadahl3, M. L. Hetland1,2, B. A. Esbensen3,1. 1Rigshospitalet, Copenhagen, Denmark; 2Copenhagen Centre for Arthritis Research, Centre for Rheumatology and Spine Diseases, Glostrup, Denmark; 3Blasiebyggen and Frederiksberg Hospitals, Copenhagen, Denmark; 4University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; 5University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

**Background:** Evidence of the positive health effects of physical activity (PA) and exercise in patients with rheumatoid arthritis (RA) is well established. Nonetheless, higher proportions of patients with RA are physically inactive compared to the general population [1]. Besides disease-related barriers to engaging in health-enhancing PA, a significant barrier may be the lack of specific PA guidance from healthcare professionals [2].

**Objectives:** The present nationwide, qualitative study aimed to explore daily PA levels and the patient’s preferences on the current and future support from health professionals (HPRs) in promoting PA in patients with RA.

**Methods:** We recruited participants from five rheumatology departments in Denmark. Recruitment was based on results from an earlier register-based cross-sectional study [3], which aimed to identify socio-demographic and clinical differences between participants and those declining participation in a RCT focusing on promoting light-intensity PA in patients with RA [4]. Accordingly, we used a purposive sampling method to ensure that interview participants varied in age, educational level, smoking status, PA levels, and disease history. Due to COVID-19, the interviews were conducted by telephone, physically, or through online platforms. Data analysis was based on reflexive thematic analysis [5].

**Results:** Of the 20 participants, 13 were female, and the mean age was 55 years (range 32–77). We generated four themes: 1) Acceptance of arthritis is a process, which was attributed to acknowledging RA as part of life as an essential mental step before the participants could fully adapt PA levels and exercise. 2) Daily physical activity – motivation and barriers, where participants described how they generally perceived PA. Also, they described their preferred intensities and types of activities as well as motivations and barriers for engaging in PA. 3) Experiences with physical activity guidance – your own responsibility? This theme reflected how participants missed to have more comprehensive and detailed discussions with HPRs in the rheumatology outpatient clinics about PA, in other words not making it a matter of their own interest and curiosity. 4) How, when and where physical activity guidance is provided is essential, which referred to the participants’ preferences and needs for future PA guidance in the rheumatology clinic, including timing, content, and location.

**Conclusion:** The study results emphasize that treating patients with RA should hold an integrated and strengthened focus on PA and exercise in routine care. However, to optimize this focus, HPRs may need adequate training in how to prioritize, guide, and motivate patients towards initiating and maintaining PA in their everyday lives.

**“IT’S LIKE LISTENING TO THE RADIO WITH A LITTLE INTERFERENCE” - MANAGEMENT OF PAIN AMONG PATIENTS WITH PSORIATIC ARTHRITIS**

**Keywords:** Qualitative research methods, Pain, Psoriatic arthritis

**N. Brodin**1, 2, 3, M. Bjork2, 4, B. Sundström3, 5, E. Svärd1, 6, Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Division of Physiotherapy, Huddinge, Sweden, 2Danderyd Hospital Corp., Department of Orthopaedics, Division of Physiotherapy, Stockholm, Sweden, 3Linköping University, Department of Rehabilitation Medicine, Linköping, Sweden, 4Linköping University, Department of Health, Medicine and Care Sciences, Linköping, Sweden, 5Umeå University, Department of Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden, 6Uppsala University/Region Gävleborg, Centre for Research and Development, Uppsala, Sweden

**Background:** Psoriatic arthritis (PsA) is an inflammatory rheumatic disease, associated with the skin disease psoriasis. Health-related quality of life is severely affected and is suggested to be so since these people have two chronic diseases at the same time, a skin disease that causes cosmetic changes and a joint disease that causes functional limitations [1]. Both international collaborations [2] and single studies of outcome measures, disease consequences and experiences of pain in PsA emphasize that pain is one of the most important areas to focus on in the assessment and treatment of this patient group [3]. To the best of our knowledge, no studies with a qualitative design exploring the management of pain from the perspectives of patients with PsA exist.

**Objectives:** To explore and describe approaches towards pain and its management among patients with PsA.

**Methods:** A descriptive design with a qualitative inductive approach was used. Semi-structured interviews were conducted with 11 participants with PsA (3 men and 8 women) recruited from one outpatient rheumatology clinic in the middle region as well as from a university hospital rheumatology clinic in the northern region of Sweden. Variation in gender, age, disease duration, activity limitation, perceived pain, fatigue, and general health was aimed at by using strategic sampling. Qualitative content analysis was used, and a pattern of theme of meaning, descriptive subthemes, and categories was constructed based on the participants’ experiences and perceptions [4, 5].

**Results:** A main overarching theme of meaning and three subthemes describing participants’ management of pain were identified. They were: ‘Taking charge of life despite the constant murmur of pain through ‘Sorting out vulnerability’, ‘Reaching acceptance and engagement’ and ‘Directing focus to change’. Nine categories further described the components of the management, ‘fear uncertainty for the future,’ ‘consider restrictions,’ ‘illuminate the invisible’, ‘increase awareness’, ‘find permissive environment and social support’, ‘enhance inner endurance’, ‘reformulate emotions and thoughts’, ‘use distracting activities’ and ‘adjust activities’ (Figure 1).

**Conclusion:** Dealing with and regulating feelings and thoughts within oneself as well as altering behavior and finding new solutions outside oneself seem to be significant for management of pain among patients with PsA. Grasping an understanding of this complex reality of living with a constant murmur of pain has the potential to improve and enhance the overall care. To support patients in taking charge of life health professionals should be able to provide team-based interventions that are underpinned by self-regulation skills and include cognitive, behavior and affective components.

**STRUCTURES THAT FACILITATE PATIENT ENGAGEMENT IN THE DEVELOPMENT AND DELIVERY OF HEALTH CARE SERVICES: A SYSTEMATIC SCOPING REVIEW**

**Keywords:** Quality of care, Systematic review, Health services research

J. Sørensen, G. Småe, A. E. Simonsen, A. Haabberstatt, I. Kjeken, H. Solvag Dagfinrud, R. H. Moel. Diakonhjemmet Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology (NKRR) REMEDY - Center for Treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway; Rayos tumsetre Rehabilitation, Patient Advisory Board, Jaren, Norway; The Norwegian Federation of Organisations of Disabled People, The Norwegian Federation of Organisations of Disabled People, Oslo, Norway

**Background:** System-level patient engagement (PE) is required to improve future healthcare services. Structures that facilitate PE are likely to be diverse and complex, but are scarcely explored and described.

**Objectives:** To identify, summarize and map research about system-level PE structures in healthcare services.

**Methods:** A systematic scoping review was conducted, searching the MEDLINE, EMBASE, Cochrane, and PsyCINFO databases. Key search elements were identified using the Population, Concept, and Context framework. The population was patient representatives, healthcare professionals, managers, and leaders. The context includes practices, motives, and outcomes, and the concept was PE in the development and delivery of healthcare services. Studies published between 2005 and 2022 were included. The coding of extracted characteristics was inspired by a PE-adapted model to evaluate the quality of healthcare services. Data was collapsed into structural attributes such as organisation, consistency, and timing of PE initiatives (Table 1), in addition to representativeness, PE knowledge, and finances.

**Results:** Of 8588 identified records, 37 studies were found to be eligible. Studies aimed to explore the impact of PE initiatives (n=8), increase knowledge and understanding about PE (n=15), and experience, attitudes, or opinions (n=9). Standing committees or panels were the most consistent PE initiatives, often acting as an established part of the structure (Table 1). Lack of PE knowledge was mentioned as a barrier in eighteen studies. Of these, eight reported that multiple stakeholders such as patients, healthcare professionals, and/or managers could benefit from increasing their PE knowledge. In twelve studies, lack of time and/or finances were listed as a barrier. High age, small numbers of patient representatives with time to spare, and professionals repeatedly recruiting the same patient representatives were described as a restriction for sufficient representativeness.

**Conclusion:** The findings indicate that the PE process may flourish through education, training, experience, and diversity among all PE stakeholders. Sufficient representativeness and PE knowledge were reported as essential structural attributes to facilitate equality and a meaningful co-creation process. Earmarked funds, sufficient to facilitate the PE structure are described as a cornerstone of integrating system-level PE in any environmental and healthcare setting.

Web, extended with the domains pain and energy. At each visit (baseline, 3 and 6 months) patients also filled out online questionnaires on goal setting, shared decision making (SDM) and PROs. PRO questionnaires included HRQoL, patient satisfaction (VAS-PSS), pain (VAS-pain), general health (VAS-GH) and daily functioning (HAQ).

At baseline also a questionnaire on coping styles was filled out.

**Results:** Ninety-two patients participated in the study. The mean age was 51 years and the most common diagnosis was rheumatoid arthritis. A total of 302 patient goals were set, of which 32% were achieved. Most goals were formulated in the domains lifestyle (14%), pain (13%) and symptoms & side-effects (13%). Fewer goals were formulated in the domains intimate relationships & sexuality (0.6%) and finances (0.3%). In the entire population, HRQoL, VAS-PSS, VAS-pain, VAS-GH and HAQ scores did not change over time. However IA patients who did not achieve their goals tended to score worse on HRQoL, VAS-PSS and HAQ after 6 months. In contrast, VAS-pain and VAS-GH showed no relation with goal attainment. The patients’ most common coping styles were active approach and comforting thoughts.

**Conclusion:** This study has raised awareness of the importance of patient goal setting. However, the goal-setting process is time consuming and, therefore, health professionals should be trained in goal setting. An online support tool which can be used in preparation for an outpatient clinic visit, can circumvent aforementioned problems. An example of such a tool is the Self-management Web, which helps patients organize and prioritize perceived problems in different domains and subsequently helps them to formulate their goals. As a result patients’ goals can be concretized immediately during the consultation, which can save time and, therefore, lower the threshold for implementation. Moreover, the incorporation of a feedback mechanism into a goal-setting intervention also seems to have a positive effect on goal attainment. Unfortunately, our intervention showed no effect on HRQoL. However, a general HRQoL measurement may not be sensitive or specific enough to detect change at this point. Possibly self-management and self-efficacy are better outcome measures. These may improve if patients actively address their problems in daily life, set goals to overcome them, and thereby manage the disease. Therefore, we recommend using more specific outcomes, or qualitative assessment of outcomes, in goal setting studies.

Conclusion: Through this scoping review, we identify that knowledge of MTX improves when education by nurses is provided. Patient education about MTX can be delivered in different forms and can result in better satisfaction and adherence. More RCTs with powered samples are required.

Although patients adapt their lives to the new conditions, they are affected by symptoms such as fatigue, pain, stiffness, and side effects such as nausea, hair loss, and weight gain. However, patients highlight the positive impact of how exercise influences their health and how living with RA gives new insights to life.

POS0794-HPR SNAPS JIA - SURVEY OF ADOLESCENTS’ NEEDS AND PARENTS’ VIEWS ON SEXUAL HEALTH IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Education, Inflammatory arthritis, Patient information and education
1CHU Clermont-Ferrand, Department of Public Health, Clermont-Ferrand, France; 2CHU Clermont-Ferrand, Transversal Patient Education Unit, Department of Public Health, Clermont Ferrand, France; 3CHU Nice, Rheumatology, Nice, France; 4APHP - Hôpital Pitie Salpêtrière, Rheumatology, Paris, France; 5CHU Grenoble, Rheumatology, La Tronche, France; 6CHU Nantes, Rheumatology, Nantes, France; 7APHP - Paris Saint-Joseph, Rheumatology, Paris, France; 8Association Francaise Spondyloarthrites, Direction, Tulle, France; 9CHU Clermont-Ferrand, Rheumatology, Clermont-Ferrand, France; 10CHU Clermont-Ferrand, Pediatrics, Clermont-Ferrand, France; 11Association KOURIR, Direction, Paris, France; 12CHU Strasbourg, Rheumatology, Strasbourg, France; 13Association nationale de lutte contre l’arthritis rhumatoïde, Direction, Clermont l’Hérault, France; 14CHU Montpellier, Rheumatology, Montpellier, France

Background: According to the world health organization, sexual health (SH) is “a state of physical, emotional, mental and social well-being in relation to sexuality”. Studies on the impact of juvenile idiopathic arthritis (JIA) on SH are scarce especially during the critical phase of adolescence. We can ask ourselves: are health professionals (HP) “good” interlocutors for JIA patients?

Objectives: We aimed to determine the expectations of JIA adolescents (10-19 years) and the perceptions of their parents regarding exchanges with HP in the field of SH.

Methods: A multicenter survey was performed in nine French rheumatology centers and three patient associations from September 2021 to April 2022, among JIA patients, aged 18-45 years and their parents. On the advice of two child psychologists and a psychiatrist, we interviewed an adult population to obtain convincing data about their adolescence with the necessary hindsight on the subject. Self-administered questionnaire interviews were designed (for JIA patients and their parents) after an extensive literature review and experts’ consensus and distributed to participants.

Results: 76 patients and 43 parents completed the anonymous questionnaires. Most patients were women (75%), with a mean age of 26 (72) years and an education level higher than high school (89%). Parents were mainly mothers (88%), with a mean age of 54 (6.6) years and an education level higher than high school (56%). Half the patients considered that JIA impacted their love life. The main causes were being in complete pain (46%) and low self-esteem (40%). The impact on their sex life was not clear-cut. Love life was discussed with parents for 52% and sexual life for 20% of patients. 59% of patients reported they were comfortable to discuss SH with an HP (yet, only 26% had done). Their main sources of information were referees (at school (48%); family (43%); or social networks (34%)). If patients reported that SH had been discussed, it was mainly when the HP was proactive (56%), with the hospital rheumatologist (50%), from a biomedical perspective. Focusing on the need for optimal care, patients and parents agreed to address SH during an individual patient education session in hospital (51% vs 35%), a regular consultation (47% vs 53%) or a dedicated consultation by request of the adolescent without parents being informed (38% vs 21%). Most patients and parents agreed that the HP should be proactive (78% vs 70%). At hospital, for patients, the most competent or the most affordable HP (yet, only 26% had done). Their main sources of information were referees (at school (48%); family (43%); or social networks (34%)). If patients reported that SH had been discussed, it was mainly when the HP was proactive (56%), with the hospital rheumatologist (50%), from a biomedical perspective. Focusing on the need for optimal care, patients and parents agreed to address SH during an individual patient education session in hospital (51% vs 35%), a regular consultation (47% vs 53%) or a dedicated consultation by request of the adolescent without parents being informed (38% vs 21%). Most patients and parents agreed that the HP should be proactive (78% vs 70%). At hospital, for patients, the most competent or the most affordable HP were the gynecologist (68%); respectively, the rheumatologist (55%); the psychologist (53%); and the psychologist (53%); 39%. Patients and parents both considered that a peer expert would make patients feel more comfortable (38% vs 37%); however, contrary to patients, fewer parents point out their skills (46% vs 25%; p=0.0276). The opportunity of a suitable moment (64% of patients vs 53% of parents), an HP comfortable with the subject (59% vs 53%), and availability of brochures (45% vs 49%) seemed to be helpful for both. The only statistically significant difference concerned HP gender, less cited by parents (7% vs 43%; p<0.0001). The use of digital resources was significantly more cited by patients than parents (video information (29% vs 9%, p=0.0127); smartphone application (25% vs 9%, p=0.0372); 79% of patients were looking for general information (impact of JIA and treatments on sexuality), discussion (68%), reassurance (65%), and listening (51%). General information (58%, p=0.0158) and discussion (39%, p=0.0022) were significantly less cited by parents.

Conclusion: To our knowledge, this is the first study to address the SH needs of adolescents with JIA. HPs should take up this real need about SH, especially in hospital for adolescents and their parents. Indeed, there are expectations directly linked to the specifics of the disease. The main difference between patients and parents would be the use of digital tools. There could be an interesting vector of communication with adolescents if the sources are reliable and parents reassured about their content.

POS0795-HPR STAGE 1 HYPERTENSION CARRIES EXCESSIVE CARDIOVASCULAR RISK IN AXIAL SpondyloarthritIS PATIENTS: A 12-YEAR LONGITUDINAL COHORT STUDY

Keywords: Self-management, Cardiovascular disease, Spondyloarthritids
J.L. H. Shi1, H. So1, S. H. M. Lam1, T. K. Li2, E. Li3, C. C. Szeto1, L. S. Tam1. 1The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China
Background: Hypertension (HT) is one of the modifiable risk factors for the development of CV event (CVE) [1,2]. The American College of Cardiology/American Heart Association (ACC/AHA) recommended a new definition for arterial HT in adults since 2017 [3]. Whether this new definition of HT is associated with increased CV risk in patients with axSpA remains unknown.

Objectives: To ascertain whether stage 1 hypertension at baseline is a predictor of future cardiovascular event (CVE) in patients with axial spondyloarthritis (axSpA).

Methods: We conducted a retrospective cohort study in axSpA patients who were recruited from 2001-2017. Patients with at least 2 years of follow-up and without prior CVE were divided into three groups according to the calculated mean BP over the first 2-year period (adjusted mean BP (≥140/90 mm Hg, 130–139/80–89 mm Hg and <130/80 mm Hg). They were followed from baseline until the end of 2020 or occurrence of a first CVE. Multivariate Cox regression analyses adjusting for baseline and time-varying variables were used to assess the relationship between mean BP and CVE.

Results: Out of the 458 patients fulfilling the inclusion criteria, 56 (12.2%) and 141 (30.8%) had an adjusted mean BP ≥140/90 mm Hg and 130–139/80–89 mm Hg respectively, and 261 (57.0%) were normotensive. After a median follow-up of 12 (7–18) years, 56 (12.2%) CVE were documented. The incidence rates were 21.4, 14.2 and 5.9 per 1000 patient-years for the three groups respectively. A adjusted mean BP of 130–139/80–89 mm Hg was independently associated with the occurrence of CVE after adjusting for the baseline covariates (Figure 1) as well as time-varying inflammatory burden (Table 1). This association was not significant after adjustment for time-varying traditional CV risk factors.

Conclusion: Stage I hypertension at baseline is associated with increased risk of developing CVE in axSpA patients. This association may be mediated by other traditional CV risk factors.

M. Törnblom1,2,3, A. Bremander1,2,4, M. Andersson1,2,6, A. Nilsson2,6, A. Kjellgren2,6, E. Haglund1,2,6
1 Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 2 Svenhult, Research and Development Centre, Halmstad, Sweden; 3 Helsingborg Hospital, Department of Rehabilitation, Helsingborg, Sweden; 4 University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 5 Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sonderborg, Denmark; 6 Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden; 7 Gothenburg University, Department of Orthopaedics, Clinical Sciences, Sahlgrenska Academy, Göteborg, Sweden; 8 Sahlgrenska University Hospital, Department of Orthopaedics, Göteborg, Sweden; 9 Halmstad University, Department of Health and Sport, School of Health and Welfare, Halmstad, Sweden

Background: Pain and functional impairment form the basis for a clinical knee osteoarthritis (KOA) diagnosis according to the National Institute for Health and Care Excellence (NICE) guidelines [1]. Enhanced knowledge of the progression from knee pain to radiographic KOA (RKOA), may enable early identification of individuals at risk.

Objectives: To study the development of radiographic knee osteoarthritis in individuals with knee pain over time, and its associations to baseline variables.

Methods: In all 172 individuals (30-67 years) with knee pain, from the Swedish HALLOA cohort (2) were studied from baseline to 2-year follow-up. The individuals at baseline coded as clinical KOA according to NICE guidelines or not. None had RKOA at baseline. At follow-up they were dichotomised as RKOA or not (Ahlbäck grade 1 or more). Self-reported knee symptoms (the Knee injury and Osteoarthritis Outcome Score (KOOS)), and knee pain intensity (numerical rating scale (NRS 0-10, best to worst) were assessed. Body composition, functional performance and clinical examination were also assessed. The Chi-Square-test or Mann-Whitney U-test was used for comparisons between groups, and logistic regression for analysis of associations between baseline variables and RKOA at follow-up adjusted for age.

Results: The mean age of the group was 51 (SD 8) years, 67% were women. Body Mass Index (BMI) was 26 (SD 5). The prevalence of RKOA at follow-up were 13% (n=23), and all of them had clinical KOA at baseline according to NICE guidelines. Furthermore, those with RKOA at follow-up had significantly higher BMI median 28.8 (IQR 8.6) vs. 25.1 (5.7), p=0.011, visceral fat area (VFA) 130.7 (88.7) vs. 84.7 (62.4), p=0.009, and knee pain; KOOS sub score (VFA) 130.7 (88.7) vs. 84.7 (62.4), p=0.009, and knee pain; KOOS sub score (ADL, 0-100, worst to best) 1.230 1.230 1.220-1.480 0.028 Bony enlargement 1.788 1.788 0.683-4.868 0.237 One-Leg Rising (number) 0.966 0.966 0.921-1.012 0.146 KOOS (Pain 0-100, worst to best) 0.964 0.964 0.937-0.991 0.091 KOOS (Symptoms 0-100, worst to best) 0.968 0.968 0.940-0.996 0.028 KOOS (ADL 0-100, worst to best) 0.969 0.969 0.941-0.989 0.039 KOOS (Sport/Rec 0-100, worst to best) 0.984 0.984 0.966-1.002 0.268 KOOS (QOL 0-100, worst to best) 0.970 0.970 0.944-0.997 0.030

POS0798-HPR PREVALENCE OF RISK FOR ANXIETY AND DEPRESSION IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Mental health, Comorbidities, Epidemiology

L. F. Vega Sevilla1, M. A. Villareal-Alarcón2, D. P. Flores-Gutierrez3, N. De Avila Gonzalez1, I. D. Hernandez-Galarza1, J. A. Cardenas-de la Garza4, D. A. Galarza-Delgado1, 5 Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: Patients with chronic diseases have a higher prevalence of anxiety and depression. The complex relationship between chronic diseases and mental health disorders can influence each other negatively. (1)

Methods: This was a cross-sectional study. Patients > 16 years old with a rheumatologic disease were included. Data from medical history were collected. The Hospital Anxiety and Depression Scale (HADS) was applied from March to November 2022. A score from 0-7 points is classified as low risk, 8-10 as intermediate risk, and >11 as high risk. Patients with high risk were referred to an evaluation by Psychiatry in the same clinic. We compared groups according to HADS scores using Kruskal-Wallis or Chi-square test.

Results: A total of 705 patients were included, 658 women, demographic characteristics in Table 1. Most common diagnosis was RA, followed by systemic lupus erythematosus (SLE). High anxiety risk was found in 125 patients, median disease duration of 6 years. Sixteen patients had high risk for depression, median disease duration of 10 years. Intermediate risk of depression was assessed in 15 patients, median disease duration of 10 years. We received 38 patients that accepted to be referred to a psychiatric evaluation. An association was found between high risk of anxiety and gender (p=0.019), no association was found with age or menopause. High risk of anxiety was more prevalent (n=125) than depression (n=16), and patients with intermediate risk for depression showed a higher prevalence of intermediate and high risk for anxiety (p=0.001).

**HPR Interventions (educational, physical, social and psychological)**

**POS0799-HPR**

**EFFECTIVENESS OF AN INTERDISCIPLINARY HEALTH PROMOTION EDUCATIONAL PROGRAM IN IMPROVING THE QUALITY OF LIFE OF INDIVIDUALS WITH FIBROMYALGIA IN BRAZIL: A RANDOMIZED CLINICAL TRIAL OF AMIGOS DE FIBRO**

**Keywords:** Patient information and education, Fibromyalgia, Self-management

M. Antunes1, F. C. N. Loures1, A. Schmitt1, E. Frutos-Bernal2, A. M. Martin-Nogueras1, A. Pasqual Marques1. 1University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOFITO), São Paulo, 2Clinica de Reumatismo Dr. Felipe Rocha Loures, Maringá, Brazil, 3University of Salamanca, Department of Statistics, Faculty of Medicine, Salamanca, Spain; 4University of Salamanca, Faculty of Nursing and Physiotherapy, Salamanca, Spain

**Background:** “Amigos de Fibro” (Fibro Friends), is a recent and innovative program created from the joint action of patients and health professionals, which can be an effective educational tool to be implemented in primary health care centers, promoting self-care, quality of life and health promotion in individuals with fibromyalgia in Brazil.

**Objectives:** Evaluate the effectiveness of an interdisciplinary health promotion educational program called “Amigos de Fibro” in improving pain intensity, symptom severity, quality of life, sleep quality and self-care agency in individuals with fibromyalgia in Brazil.

**Methods:** A randomized clinical trial was carried out with 24 participants divided into two groups: the experimental group (EG) and the control group (CG). The EG group held online meetings through the Google Meet platform with an inter-disciplinary team (10 professionals) that worked in primary health care in Brazil, where they gave lectures and held debates and dynamics on the importance of health promotion and self-care in fibromyalgia. In addition, participants performed a physical exercise protocol. The “Amigos de Fibro” protocol has been previously published and showed good agreement. The control group (CG) received an education and self-care e-book for fibromyalgia that addressed information similar to the EG (http://www.amigosdefibro.com.br). Participants were assessed pre and post-intervention. A descriptive analysis of the data was performed, as well as the differences of the independent variables between the intervention and control groups were studied using Student’s t test for independent samples.

**Results:** The mean age of the participants was 38.7±9.4 years for the EG and 34.9±10.6 for the CG, all (100%) of whom were female in both groups. Compared to the baseline, all EG variables and only the PIQ symptoms domain of the CG showed significant improvements (p<0.005), however, the other CG variables showed improvements, but they were not significant (Table 1).

**Disclosure of Interests:** None Declared.

**POSO080-HPR**

**START WITH THE END IN MIND: EMBEDDING AN INTEGRATED SELF MANAGEMENT APPROACH WITHIN ROUTINE CLINICAL CARE FOR NEWLY DIAGNOSED PATIENTS WITH INFLAMMATORY ARTHRITIS**

**Keywords:** Inflammatory arthritides, Prognostic factors, Self-management
Background: Long term outcomes of inflammatory arthritis patients are not only dependent on early identification of symptoms and tight control of disease, but also on the person’s abilities to manage the impact of their condition. (1-2) In 2019 File Rheumatology Service focussed on early identification of patient’s assets for self management (SM) and those at risk of poorer outcomes with the aim of targeting supported SM resources. EULAR 2021 recommendations endorse the implementation a self management approach within routine care[3].

Objectives:
1. Implement a SM approach as part of routine clinical care.
2. Establish baseline patient characteristics data set to evaluate the effectiveness SM interventions on long term outcomes.

Methods: Identified priorities of the re-design were:
1. Additional investment in psychology to lead the re-design.
2. SM database.
3. SM screening and triage tool, and, a SM check list.
4. Stepped model of care including referral to patient organisations.
5. Feedback from patients, staff and patient organisations.
6. Virtual weekly patient disease and SM virtual multidisciplinary team (VMDT) clinic.

Results: All 8 priorities were implemented and 315 patients have been referred to the pathway since 25/08/2022. Positive feedback about the pathway and the App has been received from patients, staff and patient organisations. Six patients at 5 months post diagnosis are discussed weekly at our VMDT clinic. Of the total patients referred, 42% were male and 58% were female. The mean age was 56 years, range 16-85 years. Twenty one percent of patients at baseline had depression on the Patient Health Questionnaire-9. Forty two percent of patients had moderate to severe disability on the Modified Health Assessment Questionnaire and 54% had moderate to severe confidence in managing their inflammatory arthritis across the 4 subsets of Emotions, Activities of daily Living (ADLS), Social Interactions and Symptoms of the Patient-Reported Outcomes Measurement Information System managing chronic conditions.(4) Lowest scores were found in the Emotions and ADLS subsets. Nineteen percent of patients of working age were not working. Twenty eight percent of patients had moderate to severe disability on the Modified Health Assessment Questionnaire and 54% had moderate to severe depression on the Patient Health Questionnaire-9. Forty two percent of patients fell into the deprived or most deprived categories of the Scottish Index of Multiple Deprivation.

Conclusion: The implementation of a self management approach as per EULAR Recommendations has been well received by key stakeholders and has helped with the early identification of patients’ SM needs and highlighted those at risk of poorer outcomes. This data will act as a basis for the application of improvement methodology to assess the effectiveness of future interventions and measure long term outcomes. Early indications would suggest targeting resources on improving patients’ confidence in managing their mental health and ADLs.

POS0801-HPR GREAT EXPECTATIONS: A FATIGUE MANAGEMENT PROGRAMME CAN ALSO IMPROVE SLEEP QUALITY AND MENTAL WELL-BEING IN RHEUMATIC DISEASE PATIENTS

Keywords: Self-management, Non-pharmacological interventions, Mental health

J. Dobson1, D. Dockrell1, K. Berg1, S. Ralston1, H. Harris2, 1University of Edinburgh, Bone Research Group, Rheumatic Diseases, Edinburgh, United Kingdom; 2NHS Lothian, Rheumatology, Edinburgh, United Kingdom

Background: Fatigue is a significant problem for patients with Rheumatic diseases and yet remains overlooked and undertreated[1-3]. It is known to be associated with increased sleep disturbance in these patients[4] and with poorer mental health[5]. A fatigue management programme (FMP) was developed with the aim of reducing the impact of fatigue on patients. Outcome measures were used to determine whether an improvement in fatigue scores also resulted in an improvement in sleep and mental health.

Objectives: The primary objective was to evaluate whether a reduction in fatigue corresponded with an improvement in sleep quality following attendance at a virtual FMP. The secondary objective was to evaluate the impact of the FMP on patient mental well-being.

Methods: The FMP was based on the RAFT study[6] and patient-reported outcome measures (PROMs) were assessed before and after enrolment to the FMP. The Visual Analogue Scale (Fatigue) (VAS-F) was used to evaluate fatigue scores. The Pittsburgh Sleep Quality Index (PSQI) was used to assess changes in sleep quality. The Patient Health Questionnaire 9-item (PHQ-9) and the Generalised Anxiety Disorder Assessment (GAD-7) were used to measure depression and anxiety scores respectively.

Results: Gender ratio 5:1 females to males, age range 25-81 with a mean of 51.6 ± 12.3. Patient’s diagnoses were equally divided between Rheumatoid Arthritis, Systemic Lupus Erythematosus and other Rheumatic Diseases. Both primary and secondary objectives have been met.

Table 1. PROM scores reported before and after the FMP. Data is shown as mean and standard deviation.

<td>5.7 ± 5.3</td>
<td>0.0005</td>
</tr>
</tbody>
</table>

Patient’s scores significantly improved in all of the PROMs collected for the purposes of this service evaluation (see Table 1). There was a correlation between improvements in VAS-F scores and improvements in PSQI scores (r = 0.365) which was statistically significant (p = 0.016).
Conclusion: An FMF is effective at significantly reducing fatigue, improving sleep quality and mental wellbeing. We have shown that there is a correlation between a reduction in fatigue and an improvement in sleep and this work highlights the importance of such a programme as part of routine care and management of these chronic conditions.

Bremander2, 3, 7, 8, 9, 10, 11, Aarhus Universitet, Health, Aarhus, Denmark; 12 University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; 13 University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 14 University Hospital of Southern Denmark, Sygehus Sønderjylland, Sønderborg, Sønderborg, Denmark; 15 Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 16 The University of Copenhagen, Faculty of Health and Medical Sciences, Department of Clinical Medicine, København, Denmark; 17 Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; 18 Spenshult Research and Development Centre, Spenshult Research and Development Centre, Halmstad, Sweden

Background: Studies show varying but beneficial effects of self-management interventions on self-efficacy, symptoms or burdens, such as pain, fatigue, illness perception, and quality of life, supporting the need of multi-disciplinary interventions in rheumatology (1, 2). However, the content of the self-management interventions differs widely (2). There is a need for an overview of the existing evidence of self-management support needs in patients with inflammatory arthritis (IA) to inform the development of relevant and effective interventions.

Objectives: 1) to identify the evidence for self-management support needs among patients with IA, and 2) to identify the content (theory/theoretical approach, mode of delivery, duration and frequency) of self-management interventions that target patients with IA.

Methods: In May 2021, we performed a scoping review (protocol published at the Open registries network, no. DOI 10.17605/OSF.IO/TVX82) and conducted a systematic literature search (from 2000 onward) in five databases.

Results: Out of 11,748 records identified, we included 31 articles describing patients’ support needs and 33 articles describing the content of self-management interventions (Figure 1). Patients’ self-management support needs were categorized into six topics: 1) Disease impact and the pharmacological treatment, 2) Care continuity and relations with health professionals, 3) The importance of non-pharmacological treatment, 4) The need for support from family and friends, 5) Support needs related to work issues, and 6) Contextual preferences for self-management support. Content of the self-management interventions varied widely and the descriptions of the content were deficient and needed clarification (Table 1). The identified topics for support needs were compared with the described content in the included articles (Table 1). Only few self-management interventions focused on patients’ need for support concerning work, family, and friends.

Conclusion: Health professionals provided self-management support to patients with IA in various ways. There were gaps between the patients’ support needs and the identified interventions. The self-management concept needs to be clearly defined when developing self-management interventions. Further studies are required to investigate various modes of delivery, frequency, and duration to develop effective interventions that meet patients’ self-management support needs.

POS0803-HPR
DEVELOPMENT OF A PATIENT-CENTERED MULTIMODAL DISEASE MANAGEMENT PLATFORM FOR THE FIBROMYALGIA-LIKE POST-COVID19 SYNDROME

Keywords: Fibromyalgia, COVID, Patient reported outcomes

M. Blanchard, T. Hügle, P. Ming Azevedo. 1Lausanne University Hospital, Rheumatology, Lausanne, Switzerland

Background: About 30% of patients with post-COVID19 syndrome satisfy the ACR survey criteria for fibromyalgia. The most common symptoms are chronic fatigue, generalized pain, sleep impairment, anxiety and depression. A substantial part of the patients already suffered from similar symptoms before infection. Digital health solutions have shown efficiency for fibromyalgia, offering specific disease monitoring and multimodal interventions and thus may work in patients with post-COVID19 syndrome.

Objectives: To develop a multimodal, multi-interventional self-management platform for post-COVID19 and potentially other post-viral syndromes patients. To ensure a patient-centric development and evaluate the usability of this solution by performing qualitative user experience research.

Methods: We developed a web-based user interface with a horizontal basic navigation menu consisting of patient reported outcomes, symptoms evolution and interventions. The therapeutic content was created by rheumatologists, physiotherapists and occupational therapists and included educational content, physical-, respiratory- and olfactory exercises, cognitive behavioral therapy, mindfulness, relaxation training, therapeutic stories and art therapy. Usability and satisfaction surveys have been conducted among 53 post-COVID19 patients and qualitative interviews have been performed.

Results: The front-end design of the platform is shown in Figure 1. 90% of the patients preferred a regular symptoms list questionnaire over a chatbot to collect patient reported outcomes. Longitudinal symptom evaluation is shown in the ‘my results’ section. 81% of patients expressed their wish that their symptoms are displayed with a benchmark of all other patients and to learn what has helped other patients with similar symptoms. A majority of them were also interested in links to patient communities (63%), so an anonymized discussion forum has been added. Patients preferred active training programs (83%) and information (59%) over interactive and gamified content like quizzes (15%). Interactivity on the web-app was created by accordion function and horizontal navigation within each treatment module. An administrator content management dashboard has been implemented to ensure a flexible and reactive supervision of the platform.

Conclusion: We present a functioning, patient-centered app tailored for patients with post-COVID19 syndrome. Further clinical studies on user experience, adherence, adoption driving factors and efficacy are ongoing.

HPR Measuring health (development and measurement properties of PROs, tests, devices)
Background: Stair climbing has been shown as the first changing activity in patients with knee osteoarthritis (KOA) [1]. Stair climbing and step tests of patients with KOA undergoing total knee arthroplasty (TKA) show asymmetrical patterns and slower climbing stairs when the affected limb is compared to the healthy limb [2]. Therefore, unilateral evaluation of the extremity undergoing TKA is important. There are many tests that evaluate stair climbing function in patients with TKA. However, the Step Up and Down (StUD) test, which was previously found to be valid and reliable in knee osteoarthritis, is a 15-second test that can evaluate the affected limb unilaterally, requires only one stair, and is similar to the daily living activities of the patients [3]. For this reason, it would be useful to use it as a criterion in the evaluation of the physical functions of individuals with TKA. However, there is no study on the validity and reliability of the StUD test in patients with TKA.

Objectives: The aim of the study is to measure the validity and reliability of the StUD test in patients with TKA.

Methods: Forty patients (Mean age; 6.87 ± 8.01) with primary TKA included in this study. The test-retest reliability of the StUD test was measured with a 1-hour interval to prevent fatigue. Validity was assessed by testing predefined hypotheses. Therefore, the 30s Chair Stand Test (30sCS), the Hospital for Special Surgery score (HSS) and Short Form-12 Quality Life Questionnaire (SF-12) were used as comparator instruments.

Results: The StUD test showed good correlation with 30sCS test (r=0.706, p<0.001), moderate to low correlation with HSS score (r=0.4, p<0.001), moderate correlation with SF12 score (r=0.508, p<0.001). Test-retest validity was excellent (ICC= 0.93, %95 CI: 0.87-0.96). Standard error of measurement and smallest real difference at the 95% confidence level for StUD test were respectively 0.34 and 0.94. There was no significant difference in the mean VAS scores measured after the tests or between the first and the second trials (p >0.05).

Conclusion: According to the results of our study the StUD test excellent reliability, good validity and high sensitivity in patients with TKA. Additionally, there was no significant increase in pain levels at the end of the test. This result suggests that StUD test can be used safely without increasing pain levels, and this test can be used reliably to monitor small changes in patients’ function.

**FACE VALIDITY AND RELIABILITY TEST OF THE DANISH VERSION OF THE COMPLIANCE QUESTIONNAIRE RHEUMATOLOGY**

Keywords: Validation, Outcome measures, Patient reported outcomes

L. Raunsbæk Knudsen1,2, A. De Thurah1,2. 1Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 2Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Background: Medication adherence in inflammatory arthritis has been reported to vary from 30% to 80%, despite the fact that non-adherence may cause worsening of symptoms and disease severity [1]. Hence, supporting adherence to medication is an essential part of the treatment and care of patients with rheumatic and musculoskeletal diseases [1]. The Compliance Questionnaire Rheumatology (CQR) measures adherence in rheumatic diseases through 19 items covering drug-taking behaviour to identify the factors that contribute to suboptimal adherence [2].

Objectives: To present the translation of the CQR into Danish and the face validity and reliability test.

Methods: The CQR was translated into Danish according to the International Quality of Life Assessment method (3), which involved forward and backward translations by four independent translators, followed by a face validity test among 10 patients with rheumatoid arthritis. The test-retest reliability of the Danish CQR was evaluated in 49 patients with rheumatoid arthritis using the standard error of the measurement (SEM) converted into the minimally detectable change (MDC) and the intraclass correlation coefficient (ICC). Questionnaires were administered with a minimum of 10 days between assessments.

Results: The face validity test did not lead to substantial corrections. The participants in the reliability test had a mean age of 57.4 years (SD 16.1) and a mean disease duration of 1.13 years (range 2 months–2 years). The mean CQR score in the test and retest was 62.69 (confidence interval (CI) 58.76; 66.6) and 62.51 (CI 58.91; 66.12), respectively, with a SEM of 8.59 (7.16; 10.73) and a MDC of 16.83. A satisfactory test–retest reliability was confirmed by an ICC value of 0.79 (CI 0.68; 0.89) (Table 1).

Conclusion: The Danish CQR has satisfactory test–retest reliability in patients newly diagnosed with rheumatoid arthritis and is thus considered a reliable tool to measure adherence in this group.

SLE, Sjögren’s and APS - aetiology, pathogenesis and animal models

A TRANSCRIPTIONAL PROFILE OF FATIGUE IN PRECLINICAL AUTOIMMUNITY WHICH IS PRESERVED IN SLE AND SJÖGREN’S SYNDROME

Keywords: Systemic lupus erythematosus, -omics, Sjögren syndrome

L. M. Carter1,2, M. Y. MD Yusof1, D. Plant1, J. Bauer1, S. Wenlock3, A. Alase1, A. Psarras1, Z. Wigston1, E. Vital1,2,3, University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom;4Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom;5University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom;6University of Cambridge, Cambridge Genomics Services, Cambridge, United Kingdom

Background: Fatigue is a prevalent and debilitating symptom in autoimmune connective tissue diseases (CTDs). Its immunological mechanisms are poorly understood. Although targeted therapies can improve fatigue, the effect is modest and variable. This is likely because, in established disease, immunological drivers of fatigue may be obscured by multifactorial effects from glucocorticoids, accrued damage and comorbidity. However, fatigue frequently pre-dates formal diagnosis or end-organ manifestations, suggesting immunological mechanisms may be better interrogated in the preclinical phase. SLE and primary Sjögren’s syndrome (pSS) are preceded by a preclinical phase of anti-nuclear antibody (ANA) positivity with no or non-specific symptoms years before clinically manifest inflammation. Although only a minority ultimately develop overt CTDs, ANA-positive individuals demonstrate complex immune dysregulation including increased interferon (IFN) pathway activation [1]. We hypothesise that immune disturbances underlying fatigue in SLE and pSS are i) established during the earlier ANA-positive preclinical phase; ii) contribute to the symptom burden among ANA-positive individuals, and iii) are differentially modulated in established disease states.

Objectives: To investigate unique and conserved peripheral blood immune cell transcriptional signatures associated with symptomatic fatigue in ANA-positive patients and establish SLE and pSS.

Methods: Bulk RNAseq was performed on peripheral blood mononuclear cells isolated from 35 ANA-positive preclinical individuals demonstrating ≤1 clinical criterion for classifiable CTD, symptom duration <12 months and naive of therapy, of whom 15 later progressed to SLE/pSS and 20 did not progress. Disease controls with SLE (n=18), pSS (n=10) were also analysed. Weighted gene co-expression network analysis was used to identity gene expression modules associated with fatigue in preclinical subjects. Consensus networks were constructed for Preclinical-SLE and Preclinical-pSS to identify fatigue-associated modular signatures which are retained in established CTDs. Gene ontology enrichment was evaluated using gprofiler.

Results: Within the preclinical transcriptomic network 5 module eigengenes showed significant and specific association with patient fatigue. A type-1 IFN signature, centred upon canonical ISGs, MX1, IFIT7, and IFIT5, was positively correlated with fatigue score (R=0.48, p<0.003) and conserved across preclinical, SLE and pSS networks, with subtly different modular organisation. One further module, enriched for RNA modification was significantly correlated with fatigue in preclinical subjects (R=0.41, p=0.01) but with no counterpart preserved in either SLE or pSS networks. The modular signature with strongest negative association with fatigue (R=-0.35, p<0.004) in preclinical subjects was enriched for mitogen-activated protein kinase (MAPK) cascades, heat shock protein and folding chaperone activity, and included transcription factors JUN and ATF3. This signature was retained in pSS patients, but did not persist in the SLE consensus network.

Conclusion: We describe novel module transcriptomic signatures associated with fatigue in the preclinical phase of autoimmunity which demonstrate differential persistence and activity in SLE and pSS. These pathways may help identify individuals with immune-mediated fatigue most amenable to therapy, and could provide insights into new therapeutic targets for fatigue across a range of autoimmune diseases.

Background: Primary Sjögren’s syndrome (pSS) is an example of an inflammatory autoimmune disorder largely mediated by IFN responses, leading to damage of exocrine glands that has been linked to autoassociative adaptive immune cells, such as Th17, CD8+ T cell and B cell [1, 2, 3]. However, the potential contribution of different innate immune cells such as Natural Killer (NK) cells and dendritic cells (DC) to pSS pathology remains understudied.

Objectives: We identify the molecular mechanisms regulating pathogenic cross-talk between NK and DC in pSS using samples from pSS patients and an experimental in vivo SS model.

Methods: Phenotypical analysis of myeloid and NK cell subsets in PBMCs from 47 pSS patients and 56 healthy donors (HD) was performed by flow cytometry. Histological analysis of SS from n=7 pSS was performed by confocal microscopy. Cytotoxic function of NK cells was assessed by culture with a K562-GFP target cell line. Transcriptional analysis of sorted Mo, CD1c+ and CD141+ cDC from four pSS patients and four HD was performed by RNA-seq. Co-culture between sorted NK cells, Mo and CD1c+ or CD141+ cDCs was used for test functional interactions. Regulation of ligands for NK cell receptors on cDC was analyzed by FACS after stimulation with poly I:C in the absence or the presence of specific siRNAs. Finally, altered DC and NK cell phenotypes and interactions with Th17 and B cells were analyzed in a murine Sjögren’s mouse model induced by poly I:C intraperitoneal injections [4] in which we used a depleting anti-NK1.1 antibody or an isotype control each 4 days.

Results: Here, we identified an enriched transcriptional CD16+ CD56– NK cell subset in pSS individuals associated with higher NK cell cytotoxic function in vitro. In addition, elevated proportions of inflammatory CD64+ CD22 exhibiting increased levels of MICA/b (p<0.01), the ligand for the activating receptor NKGD2, were observed in the blood of these patients. Cultivating cDC from pSS were capable of efficiently inducing activation of cytotoxic NK cells ex vivo and were found near CD56– NK cells in salivary glands (SG) from pSS patients. Interestingly, cDC2 from pSS were characterized by preferential transcriptional activation of IFN signatures associated to the HIG-1/1D860 pathway and its target genes. These sensors regulate the expression of MICA/b ligands on cDC2. Finally, increased proportions of CD64+ cDC2 (p<0.0001) expressing RAE-1 (p<0.01), a murine activating NKGD2 ligand, and transsional NKGD2+ CD11b+ CD56– NK cells (p=0.001) were present in vivo in the SG of an in vivo model of...
pSS. Remarkably, depletion of NK cells during the inflammation onset prevented subsequent induction of IL-17+ CD4+ (p<0.01) and memory IgD Igm CD38+ B cells (p<0.0001) in the SG.

Conclusion: Thus, our study provides novel innate immune cellular and molecular mechanisms contributing to pSS pathology and identifies new potential therapy targets.

Figure 1.

Aim of this study is to characterize metabolic changes occurring in SS SGECs and dissect the link between these changes and their acquired pro-inflammatory function.

Methods: SGECs were isolated from minor SG biopsies deriving from patients with SS and sicca. Intracellular metabolomic analysis was performed on direct ex vivo isolated primary SGECs. As read out of functional activation of SS SGECs, supernatants from SGECs cultures were collected to perform ELISA test in order to evaluate the expression of the pro-inflammatory mediator IL-6.

Results: Principal component analysis (PCA) of high-throughput metabolomics analysis of sicca (n=7) and SS (n=7) SGECs revealed a separation along the component 1 axis (46.6% of variance) indicating profound differences in the intracellular metabolome (Figure 1a). Unsupervised clustering analysis of metabolites revealed profound metabolic differences between SS and (n=7) sicca (n=7) SGECs (Figure 1b). Analysis of selected metabolites confirmed a shift towards increased glycolysis and TCA cycle activation in SS SGECs (Figure 1c). Supernatant concentrations of IL-6 were higher in SS (n=21) compared to sicca (n=14) SGECs (Figure 1d).

Conclusion: SGECs from SS patients display altered cell energy metabolism with evidence of increased glycolysis and activated TCA cycle. A metabolic driven pro-inflammatory status of SS SGECs seems confirmed by increased basal expression of IL-6. Validation of our metabolomic results, along with transcriptomic and epigenetic studies, is currently ongoing in SGECs from SS and sicca to dissect the link between changes in cell energy metabolism and their acquired pro-inflammatory phenotype.

T FOLLICULAR HELPER CELLS IN BLOOD MIRROR SALIVARY GLAND-INFLTRATING T CELLS IN PRIMARY SJÖGREN’S SYNDROME

Keywords: Sjögren syndrome, Adaptive immunity

S. Abe1, H. Tsuibo1, H. Toko1, F. Honda1, A. Koido1, H. Miki1, H. Asashima1, Y. Kondo1, Y. Matsumoto1. University of Tsukuba, Rheumatology, Tsukuba, Japan

Background: Although clonal expansion of autoreactive T cells have been identified in the peripheral blood and salivary gland of primary Sjögren’s syndrome (pSS) (1), the relationship between peripheral immune environments and inflammatory organs remains still unclear.

Objectives: Here, we examined which T cell subsets in blood share the same T cell receptor (TCR) (clonality) with T cells infiltrated at labial salivary gland (LSG) in patients with pSS, and evaluated mechanisms of their differentiation.

Methods:
1) TCR repertoire of each effector memory T cell subset (Th1, Th17, Th1, Th2) in blood, and LSG-infiltrating T cells obtained from the same pSS patient were analyzed by TCR sequence (n=1).
2) The proportion of each T cell subset in blood was compared between patients with pSS (n=30) and healthy controls (HC) by flow cytometry (n=20).

Background: Although clonal expansion of autoreactive T cells have been identified in the peripheral blood and salivary gland of primary Sjögren’s syndrome (pSS) (1), the relationship between peripheral immune environments and inflammatory organs remains still unclear.

Objectives: Here, we examined which T cell subsets in blood share the same T cell receptor (TCR) clonality with T cells infiltrated at labial salivary gland (LSG) in patients with pSS, and evaluated mechanisms of their differentiation.

Methods:
1) TCR repertoire of each effector memory T cell subset (Th1, Th17, Th1, Th2) in blood, and LSG-infiltrating T cells obtained from the same pSS patient were analyzed by TCR sequence (n=1).
2) The proportion of each T cell subset in blood was compared between patients with pSS (n=30) and healthy controls (HC) by flow cytometry (n=20).
Results:
1) LSG-infiltrating T cells, and blood Th1, Tfh1, and Tfh2 showed higher clonality than Th17, and Tfh17 cells (Figure 1). Blood Th1, and Tfh2 cells were the two most frequent subsets comprised by the same T cell clones infiltrating in LSG.
2) Blood Th1 subsets were all significantly increased in patients with pSS than in HC. Among Th1 subsets, both PD-1 and ICOS expression was highest in Th1 subsets. Furthermore, the proportion of PD-1+ICOS+Th1 cells correlated with titers of anti-nuclear antibody, anti-SS-A antibody, and anti-SS-B antibody in pSS.
3) The proportions of memory Th subsets, especially Th1, was significantly increased in LSG compared with matched peripheral blood in pSS.
4) Expression levels of CXCR5, IL-6, IL-21, and TGF-β were significantly increased in LSG compared with matched peripheral blood in pSS.
5) CD4+ T cells cultured under CD3/28 and TGF-β stimulation significantly increased CXCR5 expression, and Tfh1 population.
6) Production of IL-21, IL-2, and TNF-α were significantly increased after CD3/28 and TGF-β stimulation.
7) HC derived naïve B cells after co-culturing with pSS derived CD4+ T cells under Tfh cell differentiation condition, and effect on B cells differentiation was analyzed.

Conclusion: Tfh1 cells in blood not only frequently showed high clonal expansion, but also highly shared the same TCRβ chain with LSG-infiltrating T cells in pSS. Tfh1 cell proportion was expanded among pSS at both peripheral blood and LSGs, and furthermore, they positively correlated with autoantibody production. Notably, checkpoint molecules ICOS, TIGIT and PD1 expression correlated with PB frequencies. A Comparison of activation markers revealed increased CD86 expression on various B cell clusters of patients with SLE. Further, a memory B cell cluster expressing IgA stood out by higher KI-67 and CD45RO expression. In pSS patients, PD1+ ICOS+ CD4+ T follicular helper cell, CD8 effector memory and terminal differentiated effector memory CD8 T cell clusters were expanded. Notably, checkpoint molecules ICOS, TIGIT and PD1 were upregulated on various T cell clusters. Finally, intermedicated monocytes that express CD226 were reduced in SLE when compared to pSS.

Figure 1. T cell clonality of each sample, is shown. LSG infiltrating T cells, blood Th1, Th1f, and Th2 shows higher clonality compared to blood Th17, and Th1f17 population.

Figure 1. Workflow of the study to characterize lymphocytes using single-cell mass cytometry in SLE and pSS. (Created with BioRender.com)
Conclusion: High dimensional characterization of B, T and innate immune cells of patients with SLE or pSS illustrated immunological differences between diseases. SLE showed more B cell abnormalities while T cell alterations were more prominent in pSS consistent with distinct activation pathways driving these diseases. The immunologic abnormalities, distinct for pSS and SLE, might contribute to a better disease monitoring and selective treatment approaches.

POS0813 BINDING OF CXCL13 WITH HEPARAN SULFATE OF SYNDÉCAN-1 PLAYS AN IMPORTANT ROLE IN PATHOGENESIS OF SJÖGREN’S SYNDROME

Keywords: Cytokines and chemokines, Sjögren syndrome

G. W. Kim1, N. Y. Lee2, N. R. Kim1, S. J. Lee1, E. J. Lee1, J. A. Jang1, E. J. Nam2, G. W. Kim1

3Kyungpook National University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea)

Background: Sjögren’s syndrome (SS) is a chronic autoimmune disorder with lymphocytic infiltration in exocrine and non-exocrine epithelia, in which epithelial cells play a critical role in the initiation and amplification of inflammatory processes. Syndecan-1 (SDC-1) is a transmembrane heparan sulfate proteoglycan predominantly expressed on epithelial cells and binds to and regulates heparan sulfate-binding molecules, such as chemokines.

Objectives: In this study, we investigated the expression of SDC-1 and homeostatic chemokines and the colocalization and association of SDC-1 and B cell chemokines in mouse model of primary SS to define the role of SDC-1 in the pathogenesis of SS.

Methods: Female NOD/ShiLtJ between 6 and 12 weeks of age and sex- and age-matched C57BL/10 mice were used. Stimulated salivary flow rates (SFRs), histopathologic findings and expression of growth factor and chemokines were evaluated. Inflammation of the submandibular glands (SMGs) was assessed by the ratio index (the ratio of the area of inflammation to the total area of glandular tissue). SDC-1 level in SMGs and blood were analyzed using dot blot method. Immunofluorescence staining was performed for detection of colocalization of CXCL13 and SDC-1. For SDC-1 and CXCL13 coassociation experiments, immunoprecipitation assay was performed.

Results: The mean SFR was significantly reduced in 12-week-old NOD mice (p<0.01). Periductal inflammatory cell infiltration was detected in the SMGs in 1 of 8 (12.5%) of the 6-week-old and in all of 12-week-old NOD mice. The mean ratio index was 0.1, 4.0, 7.1, and 10.2 in the 6-, 8-, 10-, and 12-week-old NOD mice, respectively. The expression of SDC-1 in inflamed SMGs of NOD mice was elevated, especially on the ductal epithelial cells, and tended to increase as the glandular inflammation progressed. Compared to controls, the concentration of SDC-1 in the SMGs and blood of NOD mice began to increase significantly from the age of 6 weeks (SMGs, 15.6±3.6 vs. 3.5±1.2, p<0.049; Blood, 17.4±1.3 vs. 27.7±1.2, p<0.001). Compared to controls, the expression of growth factors in NOD mice was reduced, while the expression of chemokines (CXCL12, CXCL13 and IL-7) and chemokine receptors (CXCR4, CXCR5) was increased. CXCL13 and SDC-1 were detected together on the surface of glandular epithelial cells in the SMGs by immunofluorescent staining. Furthermore, colocalization of SDC-1 and CXCL13 was confirmed by immunofluorescent staining using NMuMG cells which express SDC-1 abundantly. Immunoprecipitation studies demonstrated that SDC-1 formed complexes with CXCL13, which suggested that SDC-1 binds with CXCL13 directly through heparan sulfate on the surface of glandular epithelial cells and participates in an inflammatory pathway through B cell chemotaxis.

Conclusion: These results suggested that increased SDC-1 expression in submandibular glands plays a role in the inflammatory processes through binding of CXCL13 and CXCL13 in pathogenesis of SS.

POS0813 ALTERATION OF ILC HOMEOSTATIC MAINLY CONCERNS SALIVARY GLANDS IN PRIMARY SJÖGREN’S SYNDROME

Keywords: Sjögren syndrome, Innate immunity

L. Kwak1, R. Felten1,2, C. Schleiss1, J. D. Fauny2, P. Le Van Vuyen2, H. Dumortier2, F. Monneaux2, J. E. Gottenberg1,2, Centre Hospitalo-Universitaire de Strasbourg, Rheumatology, Strasbourg, France

Background: Little is known about the early stages leading to the autoimmune process in primary Sjögren’s syndrome (pSS). Some data suggest the involvement of the innate immunity both in disease initiation and maintenance of autoimmunity in pSS, but more studies are needed to dissect the role of innate immune cell actors. Innate lymphoid cells (ILC) are a recently discovered cell population divided into three groups including type 1, 2, and 3 ILC subsets. While ILC are normally involved in the maintenance of tissue homeostasis, they can also contribute to generate tertiary ectopic lymphoid structures [1], as observed in some patients with pSS, and potentiate inflammatory processes in different chronic inflammatory diseases [2].

Objectives: The aim of this study was to analyze the frequencies of ILC subsets in the peripheral blood (PB) and quantities and location in minor salivary glands (MSG) of pSS patients.

Methods: The frequencies of ILC subsets were analyzed in the PB of 21 pSS patients and 28 healthy controls (HC) by flow cytometry: ILC were identified as CD45+, lineage (CD1a, CD3, CD4, CD14, CD16, CD19, CD34, CD303, FoxR1) and CD127+. Within the ILC gate, ILC1 were identified as c-kit+ and CRTH2+, ILC2 as CRTH2+, and ILC3 as c-kit+ and CRTH2−. The amounts and location of ILC subsets were studied in the MSG of 13 pSS patients and 5 controls (SC) using immunofluorescence. ILC were defined as lineage (CD3, CD14, CD19, CD303, FoxR1) and CD127+ cells. The expressions of T-bet (nuclear) and CRTH2 (cytoplasmic) were used to distinguish between ILC1 (T-bet+), ILC2 (CRTH2+) and ILC3 (T-bet− and CRTH2−) subsets.

Results: In PB, the frequencies of total circulating ILC and ILC subsets did not differ in pSS patients compared to HC. There was a significantly higher number of circulating ILC1 in pSS patients with positive anti-SSA antibodies (p=0.03) and a lower number of circulating ILC3 in pSS patients with glandular swelling (p=0.01). The proportions of ILC subsets in PB did not correlate with systemic disease activity measured by CliniESSDAI. Most of the ILC identified in MSG of pSS patients were ILC3 (91.1%). The amount of ILC3 was higher in tissues with lymphocytic infiltration measured by ClinESSDAI. Most of the ILC identified in MSG of pSS patients.

Conclusion: Alteration of ILC homeostasis mainly concerns salivary glands in pSS. The majority of ILC in MSG is composed by ILC3, located at the periphery of the infiltrates and were inversely correlated with the surface of T/B lymphocyte infiltrates (r=-0.42, p=0.002). ILC3 were inversely correlated with time since diagnosis (r=-0.69, p= 0.01).

UNTARGETED METABOLIC ANALYSIS OF SEBUM: A NON-INVASIVE STRATEGY TO SHOW POTENTIAL TO IDENTIFY NEW BIOMARKERS IN PRIMARY SJÖGREN’S SYNDROME AND SYSTEMIC SCLEROSIS

Keywords: Biomarkers, Sjögren syndrome, -omics

A. Hinrichs1, S. Blokland2, J. Vappiani3, A. Van Maurik3, A. Ottria1, A. Kruize3, H. Leavis2, T. Radstake4, D. Sevin3, J. Van Rooy1, UMC Utrecht, Rheumatology & Clinical Immunology/CTI, Utrecht, Netherlands; UMC Utrecht, Rheumatology & Clinical Immunology/CTI, Utrecht, Netherlands; GSK - Stevenage, Clinical Biomarker Group, Stevenage, United Kingdom; GSK - Stevenage, GSK Immunology Network, Immunology Research Unit, Stevenage, United Kingdom; Cellzome GmbH, GSK R&D, Heidelberg, Germany

Background: Saliva and tears are easy accessible fluids for biomarker analyses, but a major drawback is that a substantial proportion of patients with primary Sjögren’s syndrome (pSS) suffers from severe dryness, with limited or no saliva or tear to donate. Thus, novel non-invasive strategies applying state-of-the-art technologies should be welcomed.

Objectives: To evaluate if metabolome analysis of sebum can be used as a non-invasive method to identify skin metabolic signatures in patients with primary Sjögren’s syndrome (pSS) as compared to healthy controls and other systemic autoimmune diseases.

Methods: Untargeted metabolomics of sebum samples collected from sebatapes placed on the forehead for 5 minutes was performed using mass spectrometry. Sebum metabolomes of healthy controls (HCs, n=17) and 32 pSS patients were compared (for this abstract only ions from the negative ionization mode are discussed, for the positive ionization mode similar results were found). Additionally, the metabolomes of two other systemic autoimmune diseases, i.e. systemic sclerosis (SSc, n=21) and systemic lupus erythematosus (SLE, n=8), were compared to pSS and HCs. The human biological samples were sourced ethically, and their research use was in accord with the terms of the informed consents provided by the parent studies.

Results: Optimal significant differences were observed between the sebum metabolome of pSS patients as compared to HCs. Unsupervised dimensionality reduction using UMAP showed no strong differences between metabolic signatures of pSS patients and HCs. However, correlation analyses of metabolic changes and disease activity markers did identify several metabolite ions with a good correlation with disease activity. A total of 335 metabolite ions significantly correlated to the European Sjögren’s Syndrome Disease activity index (ESSDAI) score, 13 metabolite ions correlated with sLG and 41 metabolite ions with lymphocytic focus scores (LFS, all spearman r < 0.50 or >0.50, p<0.05). To understand if pathways in disease activity-associated metabolites may underlie the observed changes we performed pathway enrichment analyses to investigate potential group function of the metabolite ions identified in these comparisons. Two significantly enriched pathways were identified correlating to the ESSDAI score: alpha-1-macroglobulin metabolism and phenylalanine metabolism. More robust significant differences were identified in patients with systemic sclerosis as compared to healthy controls, indicating metabolites significantly enriched for pathways associated with neurotransmission, including metabolite ions with annotations as L-glutamic acid, noradrenaline, dopamine and 3'-AMP. Interestingly, when analyzing differentially expressed metabolite ions of pSS and SSc patients relative to HCs highly significant and strong correlations were observed (R=0.78 for negative ionization mode), indicating that these diseases might have common metabolic dissimilarities.

Conclusion: This pilot study demonstrates that sebum metabolomics might be a novel strategy to identify biomarkers in pSS and other (systemic) autoimmune diseases, allowing for non-invasive strategies using more targeted metabolomics strategies that take into account potential confounding factors and optimize sebum collection should demonstrate the feasibility of this novel non-invasive monitoring method in molecular profiling of disease.

Background: Dazodalibep (DAZ) is a non-antibody biologic antagonist of CD40L. In several autoimmune diseases, the CD40/CD40L pathway is activated on a variety of cell types, including T cells, B cells, disrupting the development of germinal centers, pathogenic B cells, plasma cells, and autoantibodies that are hallmarks of Sjögren’s Syndrome (SS).

Objectives: To evaluate the impact of DAZ on blood biomarkers of T and B cell costimulation in adult SS subjects with moderate-to-high systemic disease activity.

Methods: This was a randomized, double-blind, placebo-controlled, crossover study to evaluate DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity, as defined by a EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) score ≥ 5. Subjects were randomized 1:1 to receive intravenous DAZ 1500mg or placebo (PBO) Q4W x 3 doses, then Q4W x 4 additional doses (Stage 1). Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects initially randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks (Stage 2). B cell subsets downstream of T cell stimulation (Ki67+CD27+ memory, CD27 high CD38 high plasmablasts, and CD11c high atypical memory cells) were assayed via FACS throughout the study period. Serum CXCL13 concentrations, a chemokine essential for GC formation produced by activated follicular T cells, and rheumatoid factor (RF) autoantibodies were also measured.

Results: Concomitant with DAZ-related reductions in ESSDAI observed at Stage 1, significant and rapid reductions were observed in Ki67+CD27+ memory B cells, plasmablasts, CD11c+ B memory cells, CXCL13 and RF antibodies from day 15 onwards in subjects who received DAZ as compared to PBO. In Stage 2, similar reductions were found in these biomarkers when PBO-treated subjects were transitioned to DAZ treatment. In DAZ-treated subjects who were transitioned to PBO in stage 2, these biomarkers returned to baseline values while sustained reductions were observed in ESSDAI from baseline through the duration of stage 2.

Conclusion: CD40-CD40L blockade with DAZ in patients with SS reduces systemic disease activity by inhibiting T and B cell costimulation, as evidenced by treatment related reductions in blood biomarkers downstream of these pathways.

**FC, fold-change; IQR, interquartile range**
Background: Primary Sjögren's Syndrome (pSS) is characterized by the presence of antibodies (Ab). Their effector function mainly depends upon the glycan structures (14-123). Differences in sial and gal IgG levels were determined using One-way ANOVA and Kruskal-Wallis testing. P-values ≤0.05 were considered statistically significant. Bonferroni correction was applied.

Methods: The relative amount of sialylated (sial) and galactosylated (gal) IgG was determined by capillary electrophoresis after the endo-S glycosidase assay. 314 sera of the BeSSTT, an observational cohort of patients with def pSS, fulfilling the 2016 ACR/EULAR classification criteria, and of patients with suspected pSS due to presence of either objective sicca or one immunological criterion, were used. Groups were made based on the presence or absence of sicca complaints, objective sicca, anti-SSA Ab and histopathology focus score. SGUS by Hocevar was categorized in negative (0-14), low positive (15-26) and high positive (27-48) groups. Disease activity using the Eular Sjögren’s Syndrome disease activity index (ESSDAI) was categorized in low (0-4), moderate (5-13) and high (14-123). Differences in sial and gal IgG levels were determined using One-way ANOVA and Kruskal-Wallis testing. P-values ≤0.05 were considered statistically significant. Bonferroni correction was applied.

Results: Disease state was addressed in well-defined groups: patients with only sicca complaints, patients with only objective sicca, patients with only anti-SSA/SSB reactivity (prob pSS) and patients with def pSS. Def pSS patients had a significantly lower median percentage of sial and gal IgG compared to patients with only sicca complaints, only objective sicca or only anti-SSA Ab. No significant difference in sial and gal IgG was seen between the latter three groups (Figure 1). Patients with high ESSDAI had a significantly lower percentage of sial and gal IgG versus those with low ESSDAI. In high positive SGUS-score, a significantly lower median percentage of sial IgG and a lower percentage of gal IgG was noted compared to negative or low positive Hocevar score (Figure 1). Mono-anti-Ro52 reactivity, double-anti-Ro52Ro60 reactivity or triple-anti-Ro52Ro60 SSB reactivity had a significantly lower percentage of sial and gal IgG compared to anti-SSA/SSB negative. Strikingly, anti-Ro52+ and anti-Ro52Ro60 SSB+ had a significantly lower percentage of sial IgG and a lower percentage of gal IgG compared to negative or low positive Hocevar score (Figure 1).

Conclusion: These results indicate that disease state, disease activity, salivary gland involvement and serology profile is strongly associated with different levels of sial and gal IgG in pSS. This highlights the potential role for glycosylation as diagnostic marker and biomarker and its potential role in the pSS pathophysiology.

Keywords: Sjögren syndrome

A. Hinrichs, A. Kruize, F. Lefeber, H. Leavis, J. Van Rooyen. UMC Utrecht, Rheumatology & Clinical Immunology/CTI, Utrecht, Netherlands; UMC Utrecht, Rheumatology & Clinical Immunology; Utrecht, Netherlands

Background: Primary Sjögren’s syndrome (pSS) is an autoimmune disease characterized by B cell hyperactivity. CXCR5+ follicular helper T cells (Tfh), CXCR5-CD21+ peripheral helper T cells (Tph) and CCR9+ Tfh-like cells have been implicated in driving B cell hyperactivity in pSS (1-3), however, their potential overlap has not been evaluated.

Objectives: To study the overlap between the two CXCR5+ cell subsets and to study their PD-1/ICOS expression, hall markers, as compared to “true” CXCR5+/PD-1/ICOS-expressing Tfh cells.

Methods: We defined Tfh cells as CXCR5+/PD-1+/ICOS+ memory (CD45RO+), CCR9+ Tfh-like as CXCR5+/CCR9+ and CCR9+ Tfh as CXCR5+/CCR9+ memory CD4 T cells, as previously described. CXCR5+/CCR9+ co-expressing cells were not specified on memory phenotype. Tfh cells were defined as CXCR5+/mem+ and “true” Tfh cells as CXCR5+/PD-1+/ICOS+ memory cells. CXCR5- Tfh and CCR9+ Tfh-like cell populations from peripheral blood mononuclear cells of pSS patients (n=13) and age- and gender-matched healthy controls (HC, n=11) were compared by flow cytometry. PD-1/ICOS expression from these cell subsets was compared to each other and to CXCR5+ Tfh cells, taking into account their differentiation status.

Results: In pSS patients the number of Tfh cells was significantly increased compared to HC (median 0.5% versus 0.23% of CD4 T cells, p=0.049). Also the number of CCR9+ Tfh-like cells was significantly elevated in pSS patients as compared to HC, i.e. approximately 2.7% in pSS patients versus 1.7% in HC (medians, p=0.019). CCR9 expression was equally distributed between pSS patients and HC in Tfh cells. Only a modest number of 2.1% (1.2-3.2%) of Tfh cells expressed CCR9 (median with interquartile range), indicating limited overlap. CXCR5+ Tfh cells were characterized by the highest frequency of PD-1+ cells, either with or without CCR9 co-expression (PD-1+ cell frequency differed between CXCR5+/ Tfh cell subsets compared to CXCR5+/CCR9+ and CXCR5-/CCR9+ Tfh cells, both p≤0.0001). No difference in PD-1+ expression was seen between CXCR5+/CCR9+ and CXCR5-/CCR9+ cells (p=0.57). Within the PD-1+ cells, populations expressing either CXCR5+ and/or CCR9 of pSS patients showed a trend of higher ICOS expression compared to HC, but this was only significant in CCR9+ Tfh-like cells (28.6% and 55%, medians for HC and pSS, respectively, p=0.02) PD-1/ICOS expression was higher in memory cells expressing CXCR5+ or CCR9. However, the highest expression was found in CXCR5+/CCR9+ expressing T cells, which are enriched in the circulation of pSS patients. PD-1, ICOS, and PD-1/ICOS co-expression was significantly higher on CCR9+ Tfh cells than on CCR9- Tfh cells (in all three comparisons p<0.05).

Conclusion: CXCR5+ Tfh and CCR9+ Tfh-like cells are two distinct cell populations that both are enriched in pSS patients and can drive B cell hyperactivity in pSS. The known upregulated expression of CCL25 and CXCL13, ligands of CCR9 and CXCR5, at pSS inflammatory sites suggests concerted action to facilitate migration of CXCR5+/CCR9+ T cells, which are characterized by the highest frequencies of PD-1/ICOS positive cells. Hence, these co-expressing effector T cell may significantly contribute to the ongoing immune responses in pSS.

**ALTERED EXPRESSION OF RNA METHYLATION AND DEAMINATION ENZYMES IN SALIVARY GLANDS FROM SJÖGREN’S SYNDROME PATIENTS**

**Keywords:** Sjögren syndrome, Cytokines and chemokines, Genetics/epigenetics

D. Jara1, A. Aguileña2, P. Carvajal1, I. Castro, M. J. Barrera4, S. González4, C. Molina4, R. Soto-Ríos5, M. J. González1,1 Universidad de Chile, Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile; 2Clínica INDISA, Departamento de Reumatología, Santiago, Chile; 3Universidad de Chile, Departamento de Tecnología Médica, Facultad de Medicina, Santiago, Chile; 4Universidad San Sebastián, Facultad de Odontología y ciencias de la rehabilitación, Santiago, Chile; 5Universidad Mayor, Escuela de Odontología, Facultad de Medicina y Ciencias de la Salud, Santiago, Chile; 6Universidad de Chile, Programa de Virología, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile

**Background:** Primary Sjögren’s syndrome (pSS) is an autoimmune disease characterized by an overactivation of the type I interferon pathway (IFNs I) and differential microRNAs expression in the salivary glands (SG) [1]. In these patients, hasa-miR-145-5p downregulation was found to be associated with increased levels of IFNα and the overactivation of its pathway [2]. IFNs I can affect RNA biogenesis by reducing the processing of some primary microRNAs (pri-miRNAs) through diminished interaction with the microprocessor complex, leading to decreased mature microRNA levels [3]. Although the mechanisms involved are not fully understood, changes in adenosine deamination that lead to adenosine to inosine (A-to-I) editing or methylation of the N6-position of adenosines (m6A) in the pri-miRNAs could be participating.

**Objectives:** To evaluate the expression of pri-miR-145 and the enzymes that methylate (METTL3 and METTL14), demethylate (FTO and ALKBH5), and deaminate (ADAR1p110 and ADAR1p150) adenosines in RNAs of labial SG (LSG) from pSS-patients.

**Methods:** LSG from 9 pSS-patients and 6 controls as well as HSG cells stimulated with IFNα (IFN-α or IFN-β) were analyzed. pri-miR-145 levels were determined with IFNs I (IFN-α or IFN-β) and 5-methylcytosine (5mC). The enzymes localization was determined by immunofluorescence.

**Results:** LSG from pSS-patients showed increased pri-miR-145 levels, which directly correlated with the IFNs I score, a measure of the activation of the IFNs I pathway. LSG from pSS-patients also increased METTL3, ALKBH5 and ADAR1p150 levels, with no changes in METTL14 and FTO. ADAR1p150 levels also correlated directly with the IFNs I score. All the enzymes were mainly observed in the nuclei of LSG acinar cells. Finally, stimulation of HSG cells with IFNs I upregulated ADAR1p150

**Conclusion:** Increased pri-miR-145 levels suggest accumulation of this precursor in LSG of pSS-patients due to lack of processing, which could contribute to the hasa-miR-145-5p downregulation found previously (2) and could be associated to the overactivation of the IFNs I pathway. The overexpression of METTL3, ALKBH5 and ADAR1p150 could lead to changes in RNA methylation or deamination, particularly in pri-miRNAs that alter their processing, which needs further study. Finally, the functional assays suggest an association between the IFNs I overactivation and the ADAR1p150 overexpression observed in SS-patients.

**SEX-EQTL ANALYSIS REVEALS A SIGNIFICANT SEX-BIAS IN THE EFFECTS OF SJÖGREN’S SYNDROME ASSOCIATED ALLELES ON GENE TRANSCRIPTION**

**Keywords:** Genetics/epigenetics, Sjögren syndrome

G. E. Thorlacius1, A. Björk1, M. Wahren-Herlenius1,2, Karolinska Institute, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; 2University of Bergen, Department of Clinical Science, Broegelmann Research Laboratory, Bergen, Norway

**Background:** Primary Sjögren’s syndrome is a systemic autoimmune disease that affects exocrine glands, particularly the salivary- and lacrimal glands, leading to the hallmark symptoms of mucosal dryness. Patients commonly also experience fatigue, joint and muscle pain. Sjögren’s syndrome predominantly affects women, with a female-to-male ratio of 14:1. Genetic risk factors associated with Sjögren’s syndrome have been identified; however, the mechanisms behind the profound sex-bias remain incompletely understood.

**Objectives:** The aim of this study was to analyze whether the sex of a carrier of genetic variants associated with Sjögren’s syndrome affects the expression of genes in associated loci.

**Methods:** Genetically regulated gene expression differences between sexes were identified by identifying expression quantitative trait loci (eQTLs). Databases including the Genotype-Tissue Expression project (GTEx), version 8, and the NHGRI-EBI Catalog of human genome-wide association studies (GWAS catalog) as well as a literature review were utilized to extract information about variants significantly associated with Sjögren’s syndrome, and their sex-specific eQTL effects.

**Results:** Out of 22 non-HLA loci identified as associated with Sjögren’s syndrome at the genome-wide level, 4 independent loci had one or more significant sex-eQTL effects in the GTEx database in any tissue. These included variants near IRF5, TNIP1, SYNGR1 and the BLK-FAM167A loci. Additionally, variants in 4 Sjögren’s syndrome associated loci within the HLA region on chromosome 6 were found to have one or more sex-eQTL effects in the GTEx database. Of the 14 identified sex-eQTLs for Sjögren’s associated loci, 10 were female biased.

**Conclusion:** Sjögren’s syndrome is a female biased disease and genetic variants associated with Sjögren’s syndrome have discordant effects on gene expression in females compared to males. A majority of the identified effects point towards a more severe effect of these variants in female carriers than male carriers, indicating that females could be more profoundly affected by these genetic risk factors than males. This suggests a mechanism where genetic risk factors could disproportionately increase disease risk in one sex compared to the other.

 Conclusion: We identified DEGs through bioinformatic and functional enrichment analysis. 10 genes appeared in different datasets, while 21 were listed as their co-expressed pairs. These genes play a fundamental role in the processes of Defense response to virus, Response to virus and Negative regulation of the viral genome. Most of them belong to the type I IFN signature. An in vivo analysis in patients with primary SS is needed to validate these genes as possible diagnostic biomarkers and even possible therapeutic targets.

</table>

Background: Biological disease-modifying antirheumatic drugs (bDMARDs) and janus kinase inhibitors (JAKi) are generally more effective combined with methotrexate (MTX) in patients with rheumatoid arthritis (RA). However, in clinical practice, bDMARDs/JAKi is sometimes used without MTX for such as elderly patients with poor renal function. To date, there are few reports evaluating ultrasound finding of intra-articular synovitis in patients with RA treated bDMARDs/JAKi with or without MTX.

Objectives: Ultrasound finding of intra-articular synovitis in patients with RA treated bDMARDs/JAKi with or without MTX was compared by using propensity score matching.

Methods: A total of 750 RA patients who underwent ultrasound examination were included. Ultrasound examination was performed at the orbital bone to first voluntary metacarpophalangeal (MCP) joints, fingers interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints. Of all 750 RA patients, 517 RA patients (68.9%) who treated bDMARDs/JAKi were divided into with or without MTX. Then, patients were matched using the propensity score adjusted for age, sex, duration of RA, disease activity (CDAI), CRP level, and MMP-3 level. The total gray scale (GS) and power Doppler (PD) score (GSUS/ PDUS) were compared between bDMARDs/JAKi treated patients and without with MTX.

Results: There were 159 (30.8%) patients without MTX and 358 (69.2%) patients with MTX. The 151 patients in each group were matched. The mean MTX dose of bDMARDs/JAKi with MTX group was 8.8±3.5 mg/week. Patients’ characteristic of bDMARDs/JAKi without MTX and bDMARDs/JAKi with MTX were shown in Table 1. Ultrasound synovial findings were significantly suppressed in the MTX group. GSUS 11.6 ± 11.8 vs 8.5 ± 8.0 (p = 0.009) and PDUS 8.3 ± 9.9 vs 5.5 ± 6.2 (p = 0.004). Moreover, US findings were compared in TNF user, non-TNF user and JAKi user. Notably, ultrasound findings were worse in non-TNF inhibitor users without MTX.

Figure 1. Ultrasound findings of bDMARDs/JAKi without MTX and bDMARDs/JAKi with MTX.

Figure 1. Topologic analysis displaying the Interferon Signature.
Conclusion: Ultrasound synovial findings in patients with bDMARDs/JAKI were more suppressed with MTX. It was considered necessary to keep in mind that synovitis may persist in patients who are not concomitant with MTX and are using anti-NTF inhibitors.

UPTAKE OF INFLIXIMAB BIOSIMILARS AMONG U.S. RHEUMATOLOGY PRACTICES THROUGH 2022

Keywords: Registries, bDMARD, Epidemiology

J. Yazdany1, J. Li2, E. Roberts3, R. Stovall4, G. Schmajuk1. 1University of California, San Francisco, Medicine/Rheumatology, San Francisco, United States of America

Background: The first infliximab biosimilar (infliximab-dybb) entered the U.S. market in 2016 and two additional products are now available (infliximab-axxq and infliximab-abda). Biosimilars have significant potential to slow drug spending; however, biosimilar uptake in the U.S. has lagged. Little is known about the impact of additional infliximab biosimilar approvals on market penetration or about patterns of use among rheumatologists.

Objectives: We used the national RISE registry 1) to examine uptake of infliximab biosimilars between 2016 and 2022 and 2) to study physician prescribing of these drugs. For the latter, we analyzed patterns of biosimilar drug use across a national sample of practices and analyzed characteristics of patients who were prescribed biosimilars vs. bio-originator infliximab.

Methods: Data from RISE, a national registry that includes electronic health records from one-third of U.S. rheumatology practices, was used. All bio-originator or biosimilar infliximab administrations (of any dose) between April 2016 and March 2022 were analyzed. We included patients 18 years or older who had at least one visit with a rheumatologist; all infliximab bio-originator or biosimilar users, regardless of diagnosis, were included. To assess the uptake of biosimilar infliximab, we examined the proportion of patients using each formulation (infliximab, infliximab-dybb, infliximab-abda and infliximab-axxq) in 2-month intervals during the study period. Patients were included in multiple time windows if they received different products during the study period. Next, we examined practice-level uptake of biosimilars among practices with ≥ 20 new infliximab users after 2019. Finally, we examined the characteristics of patients who were prescribed biosimilars. For this analysis, we calculated standardized mean differences (SMDs) to permit comparisons of the characteristics of users of bio-originator infliximab and each biosimilar. In cases where more than one infliximab product was prescribed, patients were classified based on their most recent infliximab prescription.

Results: During the study period, 32,916 individuals used bio-originator infliximab, 3,999 used infliximab-dybb, 1,369 used infliximab-abda, and 1,099 used infliximab-axxq. Figure 1 demonstrates that uptake of biosimilar infliximab formulations remained below 20% and rose only minimally with the introduction of new biosimilar formulations in 2017 and 2020. Among 102 rheumatology practices with ≥ 20 new infliximab users, we observed significant variability in biosimilar use. 16.6% of practices had no patients on biosimilars, 27.4% had between one and ten percent of patients on biosimilars; only 15.6% had more than half of patients on biosimilars, SMDs for age, sex, race and ethnicity, insurance, region, and rheumatic disease diagnosis were all ≤ 0.5, indicating only small differences in patient characteristics across different formulation groups when comparing bio-originator infliximab to biosimilar versions.

Conclusion: Uptake of biosimilar infliximab drugs has been slow and minimally impacted by the introduction of additional biosimilar formulations in the U.S over the last six years. Only a small percentage of rheumatology practices use biosimilars for most patients, and a substantial proportion do not use biosimilars at all. We noted only small differences in patient characteristics between bio-originator and biosimilar infliximab users, suggesting that patient demographic characteristics, geographical region, diagnosis and insurance are not major drivers of prescribing differences. These findings suggest that in the absence of mandatory switching policies or other incentives, the U.S. has largely failed to achieve a robust biosimilars market, stymieing efforts to increase competition and reduce cost.

Figure 1. Proportion of patients in the RISE registry using infliximab bio-originator or biosimilars between 2016 and 2022.

Background: FIL is a Janus kinase (JAK) 1 preferential inhibitor for the treatment of RA. Data from the ORAL Surveillance post-marketing study (NCT02092467) suggest that in patients with active RA aged ≥50 years with ≥1 CV risk factor, the risks of cancer and major adverse cardiovascular events (MACE) are higher with the pan-JAK inhibitor tofacitinib vs tumor necrosis factor inhibitors, with higher rates in those aged ≥65 vs <65 years.[1]

Objectives: To assess the incidence of malignancies excluding non-melanoma skin cancer (NMSC), NMSC, MACE and venous thromboembolism (VTE) in patients treated with 200 mg FIL200 and FIL 100 mg (FIL100) in RA clinical trials.

Methods: Data were pooled from patients treated with FIL200 or FIL100 from DARWIN 1–3 (NCT01889874, NCT01984516, NCT02065700) and FINCH 1–4 (NCT02889796, NCT02873936, NCT02886728, NCT03023308). Data cuts used for the ongoing DARWIN 3 and FINCH 4 studies were May 2, 2022, and May 6, 2022, respectively. Exposure-adjusted incidence rates (EAIRs) per 100 patient-years of exposure (PYE) were calculated for MACE, VTEs, malignancies
excluding NMSC, NMSC and treatment-emergent adverse events (TEAEs) lead-
ing to death, according to FIL dose (200 vs 100 mg) and age (<65 vs ≥65 years); no statistical testing was performed, so all differences are numerical. MACE and VTE were adjudicated by an independent committee; the cutoff for adjudication was April 3, 2022.

**Results:** Overall, 3691 patients were treated with FIL for a total of 12,541 PYEs. Median (max) PYE was 3.8 (8.3) years for FIL200 and 3.3 (7.8) years for FIL100. Baseline characteristics are shown in the **Table 1.** A greater proportion of those aged ≥65 years vs <65 years had a CV medical history in both the FIL200 (75.7% vs 38.1%) and FIL100 (71.8% vs 40.9%) groups. Overall EAIRs (95% confidence interval [CI]) were 0.40 (0.3, 0.5) for MACE, 0.19 (0.1, 0.3) for VTEs, 0.69 (0.6, 0.9) for malignancy excluding NMSC, 0.29 (0.2, 0.4) for NMSC and 0.65 (0.5, 0.8) for TEAEs leading to death. EAIRs of MACE and VTE were higher in patients aged ≥65 vs <65 years but were generally similar for FIL200 and FIL100 within each age group (**Figure 1**). EAIRs of malignancies, NMSC and TEAEs leading to death were higher in the ≥65- vs <65-year group of the FIL200 group, EAIRs (95% CI) of these events were numerically higher in the FIL200 vs FIL100 group: 2.0 (1.3, 2.9) vs 0.99 (0.5, 1.9) for malignancies, 1.38 (0.8, 2.2) vs 0.44 (0.1, 1.1) for NMSC, and 1.59 (1.0, 2.5) vs 1.20 (0.6, 2.2) for TEAEs leading to death, respectively.

**Conclusion:** Rates of MACE and VTE in FIL-treated patients were low and similar for FIL200 and FIL100. There was a higher proportion of patients aged ≥65 years vs <65 years with a CV medical history. In patients aged ≥65 years, EAIRs of malignancies, NMSC and TEAEs leading to death were higher with FIL200 vs FIL100, although CIs overlapped.

**Background:** Concerns regarding the risk of cancer with janus kinase inhibitor (JAKi) use in patients with rheumatoid arthritis (RA) escalated after the release of results from Pfizer’s clinical trial, ORAL Surveillance.[1] The trial showed increased risks of major adverse cardiovascular events and cancer in tofacitinib compared with tumour necrosis factor inhibitor recipients. Precautionary considerations on JAKi use in high-risk subsets of patients with RA have since been issued by the European Medicines Agency.
Objectives: We aimed to investigate the risk of first primary cancer in patients with RA treated with JAKi (tofacitinib and baricitinib) compared with those who received biologic disease-modifying anti-rheumatic drugs (bDMARDs) in a real-world setting.

Methods: We performed an observational cohort study using the nationwide registers in Denmark. Patients with RA aged 18+ years, without a previous cancer diagnosis, and who initiated treatment with JAKi or bDMARDs from 1 January 2017 to 31 December 2020 were identified in the Danish Rheumatology Quality Register (DANBIO) and followed for any cancer (except non-melanoma skin cancer) with a 2:1 ratio of patients with cancer in the JAKi and bDMARD groups, respectively. The JAKi group contributed with 1315 person years (PYRS) and 19 cancers, while the bDMARD group contributed with 8857 PYRS and 111 cancers. The corresponding crude incidence rates per 1000 PYRS for cancer were 14.4 (JAKi) and 12.9 (bDMARD). Comparing the two groups using weighted CSC models, a HR of 1.41 (95% CI 0.76 to 2.37, 95% confidence intervals) was seen for JAKi- versus bDMARD-treated patients with RA.

Conclusion: JAKi treatment in real-world patients with RA was not associated with a statistically significant increased risk of first primary cancer compared with those who received bDMARDs. However, risk estimates were elevated in many analyses, and an excess risk of cancer with JAKi treatment cannot be ruled out. More studies investigating JAKi and cancer risk in patients with RA are highly warranted.

REFERENCE:

More studies investigating JAKi and cancer risk in patients with RA are highly warranted.

Any AE leading to study drug discontinuation (E/100 PY (95% CI))
special interest (AESI). Data were analysed for the periods in which pts who dis-
continued study drug received 1) tofacitinib or TNFi (randomised period) and 2) SOC treatment (SOC period); Pts were analysed in their original treatment group (ex-tofacinib 5/10 mg BID, or ex-TNFi). Analyses were descriptive.

**Results:** Of 4362 randomised and treated pts, 718 (16.5%) stopped study treatment (50.7, 59.3 and 47.8% due to AESI; 15.1, 5.8 and 21.9% due to insufficient clinical response for tofacitinib 5 mg BID, 10 mg BID and TNFi, respectively); most received csDMARDs only in the SOC period (73.1–79.6% across groups). In general, BL characteristics in pts who switched to SOC treatment were numerically similar across groups. Mean duration of randomised and SOC periods was 21.9–36.0 and 15.0–18.6 months, respectively. ASDAI over time was similar across groups in the randomised period (data not shown) with modest improvements in the SOC period (Figure 1) and with SDAI score generally reflecting moderate disease activity (data not shown). In general, AE and SAE rates were similar across groups but numerically higher in the randomised vs SOC period (data not shown). AESI rates were generally similar across groups in the SOC period (Table 1).

The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, United States of America

**Background:** In ORAL Surveillance, a post-approval safety study conducted in RA patients aged ≥50 years with ≥1 cardiovascular (CV) risk factor, non-inferiority was not shown for MACE and malignancy (excluding nonmelanoma skin cancer) for tofacitinib versus TNFi inhibitor (TNFi) therapy.[1] A post hoc analysis of the ORAL Surveillance data suggested that patients with a history of atherosclerotic cardiovascular disease (ASCVD) were most at risk relative to TNFi.[2] Whether these findings are characteristic of the entire JAK inhibitor class is unclear.

**Objective:** To evaluate the impact of baseline ASCVD risk on the incidence of MACE with upadacitinib (UPA) versus TNFi and MTX in an RA population similar to ORAL Surveillance from the SELECT RA clinical program.

**Methods:** Post hoc analysis of adjudicated MACE was performed in two patient populations pooled across six SELECT phase 3 studies: the overall population and the higher CV risk subset (patients aged ≥50 years with ≥1 CV risk factor). Patients received UPA 15 mg once daily (with or without conventional synthetic DMARDs), adalimumab (ADA) 40 mg in combination with MTX, or MTX monotherapy. CV risk factors used to identify the higher-risk patients included prior CV event, hypertension, diabetes mellitus, current or former tobacco/nicotine use, and baseline HDL-C levels ≤40 mg/dL. Patients were further stratified based on medical history of ASCVD, which included coronary artery disease and other relevant events (e.g., arteriosclerosis, ischemic stroke, and carotid artery disease). In patients without a history of ASCVD, 10-year ASCVD risk categories were calculated with a 1.5 multiplier applied.[3] Exposure-adjusted incidence rates (EIRs) per 100 patient-years were summarized based on the treatment received; 95% CIs were determined based on the exact method for the Poisson mean.

**Results:** Of 4102 enrolled patients (UPA 15 mg, n=3209; ADA, n=579; MTX monotherapy, n=314), approximately half were aged ≥50 years with ≥1 CV risk factor (n=2199 total; UPA 15 mg, n=1717; ADA, n=320; MTX monotherapy, n=162). In the overall SELECT population, EIRs of adjudicated MACE were 0.3, 0.3, and 0.2 n/100 PY for UPA, ADA, and MTX groups, respectively (Figure 1). Rates of MACE were higher in UPA-treated patients with a history of ASCVD (19 n/100 PY) compared to those without a history of ASCVD (0.2 n/100 PY) in the overall population. No occurrences of MACE were reported with ADA or MTX in patients with a medical history of ASCVD, possibly due to the limited patient numbers in these groups. Among patients with no history of ASCVD in the overall population, higher rates of MACE were observed for patients in the high or intermediate 10-year ASCVD risk categories versus the low or borderline risk category, irrespective of treatment. In the higher CV risk subset of the SELECT population, rates of MACE were numerically higher than the overall population but were similar between treatment groups (0.6, 0.5, and 0.5 n/100 PY for UPA, ADA, and MTX groups, respectively). Consistent with the overall population, the incidence of MACE was higher among UPA-treated patients with a history of ASCVD relative to those without a history of ASCVD. The rates of MACE in the higher-risk population were also generally similar across treatment groups for patients within each of the different 10-year ASCVD risk groups.

**Conclusion:** In this post hoc analysis, higher rates of MACE were observed in UPA-treated patients with a history of ASCVD versus those with no history of ASCVD. In both the overall SELECT population and the higher CV risk subset, rates of MACE were generally comparable between UPA and ADA in the
different ASCVD risk categories. However, given the low sample size and limited patient-years of exposure in ADA and MTX treatment groups, results should be interpreted with caution.

Background: DARWIN 3 (NCT02065700) is a long-term extension (LTE) study assessing the safety and efficacy of filgotinib (FIL) in patients with rheumatoid arthritis (RA) and an inadequate response to methotrexate (MTX). [1] In the DARWIN 1 (NCT01888674) and DARWIN 2 (NCT01894516) parent studies, patients received FIL in combination with MTX or FIL monotherapy, respectively.

Objectives: To provide an update on the safety and efficacy of FIL 200mg (FIL200) in patients with RA, with or without MTX, with a maximum of 8.2 years of exposure.

Methods: Patients completing the DARWIN 1 (FIL + MTX) and DARWIN 2 (FIL monotherapy) phase 2 studies could enter DARWIN 3, receiving FIL200. The proportion of patients experiencing treatment-emergent adverse events (TEAEs) were reported using the safety analysis set, comprising data from both the parent and LTE studies. Efficacy was assessed from LTE baseline using the American College of Rheumatology (ACR) 20/50/70 improvement criteria and Disease Activity Score in 28 joints–C-reactive protein (DAS28-CRP), up to 264 weeks. Low disease activity and remission were defined as DAS28-CRP <3.2 and <2.6, respectively.

Results: In total, 739 patients were enrolled in DARWIN 3. Mean (standard deviation; SD) FIL exposure was 4.89 (2.72) years in the FIL + MTX group and 4.78 (2.79) years in the FIL monotherapy group. In the FIL + MTX vs FIL monotherapy groups, TEAEs were reported for 90.9% and 92.1% of patients, respectively (Table 1). The most common TEAE was infection. In both treatment groups, 8 patients had a TEAE leading to death (1.6% and 3.3%, respectively). Exposure-adjusted incidence rates, censored at time of first event for major adverse cardiovascular event, venous thromboembolism, herpes zoster, infections, serious infections, non-melanoma skin cancer (NMSC), malignancies excluding NMSC, gastrointestinal perforations and TEAEs leading to death, will be reported. Through 5 years, ACR20/50/70 responses were maintained in 86.3%/66.7%/50.7% of the FIL + MTX group and 90.8%/74.8%/51.4% of the FIL monotherapy group, respectively (observed data). DAS28-CRP low disease activity and remission rates (non-responder imputation) at DARWIN 3 baseline were 46.1%/40.1% (FIL + MTX) and 29.6%/24.8% (FIL monotherapy) (Figure 1). At Week 264, the proportion of patients achieving low disease activity and remission were 34.0%/34.3% (FIL + MTX) and 27.0%/24.8% (FIL monotherapy).

Conclusion: With a maximum of 8.2 years of exposure in patients with RA, the FIL safety profile is similar between the background MTX and monotherapy treatment arms. Both arms show sustained efficacy over time.

BARICITINIB VERSUS TNF-INHIBITORS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO CsDMARDs: 12 WEEKS RESULTS OF A PRAGMATIC, MULTICENTER, OPEN LABEL, NONINFERIORITY TRIAL

Keywords: Randomized control trial, Targeted synthetic drugs, Real-world evidence

M. O. Voshaar1, P. Ten Klooster2, D. Tedjo3, C. Van de Laar4, M. Van de Laar5.

1University of Twente, Medical Cell BioPhysics & TechMed Center, Enschede, Netherlands; 2University of Twente, Department Psychology, Health and Technology, Enschede, Netherlands; 3Transparence in Healthcare, -Hengelo, Netherlands; 4Erasmus University Rotterdam, Erasmus School of Health Policy and Management, Rotterdam, Netherlands; 5University of Twente, Department Psychology, Health and Technology, Enschede, Netherlands

Background: The EULAR guidelines for RA recommend that treatment should be aimed at reaching a predefined disease activity target (T2T). If this treatment target is not achieved with csDMARD, adding a TNF or a JAK-inhibitor are advised options in patients with poor prognostic factor, obviously considering contraindications. While randomized clinical trials have provided relevant data on the relative efficacy and safety of TNFi and JAKi under ideal conditions, the extent to which such results can be generalized to real-life clinical practice conditions remains unclear.

Objectives: To demonstrate non-inferiority (NI) and, in case NI could be shown, superior efficacy of a T2T strategy in which csDMARDs refractory RA patients failing to respond to csDMARDs were eligible if they were pretreated according to T2T principles, had a disease duration <5 years and no contraindications to b/tsD-MARD. All included patients were treated open label at the discretion of their treating rheumatologist with either TNFi (any type) or baricitinib. Patients were seen at baseline and 12-weekly until final follow-up (48 weeks). Full clinical assessment was performed at each visit. Self-report questionnaires, including PROMs, were collected as well. The primary endpoint was defined as NI of baricitinib versus TNFi in the proportion of patients achieving ACR50 response at week 12, with subsequent superiority testing in case non-inferiority was shown. For the primary efficacy analysis, the proportion of patients achieving ACR50 response were compared, using 95% confidence intervals calculated using the Wilson score method. The non-inferiority margin for baricitinib was set at -12%.

Results: 199 patients who received a first dose of either TNFi (102) or baricitinib (97) were included. Baseline characteristics were comparable between both groups (see Table 1). At 12 weeks, the lower bound of the 95% confidence interval for the difference in proportions of patients meeting the ACR50 response is to the right of zero in both the per-protocol and intention-to-treat analysis (see Figure 1). Hence, baricitinib was found to be non-inferior and statistically superior to TNFi in the analysis of the primary endpoint. Moreover, DAS28 remission (DAS28-CRP <0.36) was achieved in 74% of baricitinib patients compared with 46% of TNFi patients (p<0.001) at 12 weeks.

Conclusion: Baricitinib was found to be non-inferior and superior to TNFi in terms of ACR50 response at 12 weeks in real-world csDMARD refractory RA patients. Analysis of secondary endpoints, disease activity across other measurement points, PROMs, radiology, safety and costs is currently ongoing.
Background: Patients with IIM, and notably patients with rheumatoid arthritis (RA), are at increased risk of cancer compared with the general population [1,2]. It is hence paramount to assess the impact of biological or targeted DMARD (e.g., tofacitinib and TNF inhibitor) on the risk of cancer outcome in patients already at-risk, particularly in the context of ORAL Surveillance which showed a higher risk for malignancies (excluding nonmelanoma skin cancer, NMSC) with tofacitinib, in comparison with TNFi, in RA patients [3].

Objectives: To assess the impact of tofacitinib and TNFi on the risk of malignancies in patients with RA treated in real-world clinical practice.

Methods: The RELATION study is a retrospective observational cohort study using the French nationwide healthcare database (SNDS). Patients aged 18 years or older, affiliated to the national health insurance with a diagnosis of RA and initiating tofacitinib after November 1, 2017 or TNFi after January 1, 2010 (including adalimumab, etanercept, or other TNFi, without previous exposure to tofacitinib) were followed from treatment initiation to December 31, 2020. Patients with a previous history of a malignancy (excluding NMSC) in the 4 years preceding cohort entry were excluded. All malignancies events were defined by the first hospitalization for malignancy during follow-up. Comorbidities and traditional cardiovascular (CV) risk factors were identified using hospitalizations, procedures, or medication dispensing in the 4 years prior cohort entry. The unadjusted incidence rate (IR) of malignancies (excluding NMSC) was assessed in patients initiating either tofacitinib or a TNFi (with associated 95% confidence intervals [95% CI]). A 1:3 PS matching was conducted to balance the baseline characteristics of patients initiating tofacitinib and TNFi. Cox proportional hazards regression models were used to compare the risk of malignancy with tofacitinib vs TNFi during the follow-up period.

Results: Between 2010 and 2020, a total of 39,578 patients with RA were included in the study. Among these, 2,811 initiated tofacitinib and 36,767 initiated a TNFi (adalimumab: 10,621, etanercept: 16,512, other TNFi: 9,634). Patients had a mean age of 53 years at cohort entry, and 72% to 81% were women. Around 61% of the cohort had at least one CV risk factor (66.3%/for tofacitinib compared to 60.9% for TNFi). The two major co-medications at treatment initiation in the two groups were metformine (60.9%) and corticosteroids (50.8%). After PS matching, the tofacitinib cohort included 2,628 patients, and the TNFi cohort included 7,884 patients. Over a median follow-up period of 11.31 months (tobafcitinib: 8.56 months, TNFi: 12.52 months), 15 incident malignancy events were occurred in the tofacitinib group (IR: 3.55–9.77) per 1,000 patient-year (PY)) and 135 occurred in the TNFi group (8.03 (6.78–9.50)). The risk of malignancies (excluding NMSC) in comparison with TNFi, in RA patients treated in real-world clinical practice is hence paramount to assess the impact of biological or targeted DMARD (e.g., tofacitinib and TNFi) on the risk of malignancy.

References:
Background: Intersitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept and rituximab are the recommended drugs [1-2]. JAK inhibitors (JAKI) have demonstrated efficacy in RA. However, in clinical trials patients with active ILD were usually excluded. Moreover, a warning on ILD toxicity is included in SmPC (Summary of Product Characteristics) drugs.

Objectives: to assess a) the effectiveness and b) the safety of JAKI in AR-ILD patients. Methods: National multicenter study of 57 RA-ILD patients on treatment with JAKI. We analysed from baseline the following outcomes: a) forced vital capacity (FVC), b) diffusion capacity of the lungs for carbon monoxide (DLCO), c) hypoxemia at rest (SatO2), d) dyspnea (Medical Research Council scale), e) arthritis activity (DAS28-ESR or clinical records), and f) sparing corticosteroids effect. Results: We studied 57 patients (37 women/20 men; mean age 66 ±10 years) from 9 hospitals in Spain. Baseline demographic and clinical characteristics are shown in Table 1. All patients had received disease-modifying antirheumatic drugs (DMARDs) before JAKI (Methotrexate (49,86%), Leflunomide (37, 65%), Sulphasalazine (14, 25%), Hydroxychloroquine (13, 23%), Abatacept (32, 56%), Tocilizumab (14, 25%) and Rituximab (10,18%). Most patients were on BARI (29, 51%), Hydroxychloroquine (13, 23%), Abatacept (32, 56%), Tocilizumab (17, 30%), Methotrexate (49, 86%) and Leflunomide (37, 65%) and sparing corticosteroids effect. Conclusions: JAKI, especially BARI, may be useful and safe in controlling the course of both pulmonary and joint disease in RA-ILD patients, even in refractory cases.

Results: At baseline, endothelial function was impaired and levels of inflammatory measures were elevated and HAQ-DI was impaired in both groups. After treatment, FMD improved significantly in the tofacitinib group from (6.6±2.13 to 8.17±2.69, p=0.0001) as compared to placebo (6.36±3.01% to 6.84±2.95%, p=0.68) (Figure 1A). DAS28 (Figure 1B), ESR and CRP levels improved significantly in tofacitinib group as compared to placebo (p<0.05). TOFA significantly decreased HAQ-DI (Figure 1C) values as compared to placebo. There was no MACE or VTE event during the study period in either group. After 12 weeks of treatment, FMD increased by 23.04% where as DAS28, ESR and CRP decreased by 31.23%, 29% and 60% respectively in the TOFA group (Figure 1D). Significant negative correlation was observed between FMD and CRP (r=0.32, p<0.05) before and after (r=-0.34, p<0.05) treatment with TOFA whereas no such correlations were found in placebo group.

DOI: 10.1136/annrheumdis-2023-earl.5291
Conclusion: TOFA, apart from its anti-inflammatory activity, improves endothelial dysfunction and cardiovascular risk in active RA without clinical overt cardiovascular disease. Thus, JAK inhibition with TOFA has vasculoprotective and cardioprotective effects mediated through anti-inflammatory and probably other mechanisms.

POS0839 AGOMELATINE IDENTIFIED FROM THE FDA-APPROVED DRUG LIBRARY IS THERAPEUTIC AGAINST COLLAGEN INDUCED ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines

Y. Chen1,2, Y. Tian1, H. Liu1,2, Q. Li1, Z. Luo1, G. Yin1, Q. Xie1. 1West China Hospital, Sichuan University; Department of Rheumatology and Immunology; Chengdu, China; 2West China Hospital, Department of Rheumatology and Immunology; Chengdu, China

Background: Treatment effect of tumor necrosis factor α (TNFα) inhibitors is still low in patients with rheumatoid arthritis (RA), around 50%-70%. Thus more drugs by targeting proliferation of synovial fibroblasts (FLS) and TNFα induced inflammatory cytokine production are needed. Repurposed use of drugs that have been used in clinic is a quick and cost-effective way to find new drugs.

Objectives: This study aims to screen drugs that could inhibit the proliferation and inflammation induced by TNFα in FLS from FDA approved on market drug library, then to assess the treatment effect of the identified drugs on collagen-induced arthritis (CIA) mouse model.

Methods: CCK8 assay was performed to screen the drugs that could inhibit FLS proliferation, followed by qRT-PCR and ELISA to select the drugs that could suppress TNFα induced inflammatory cytokine production. Then, treatment effects of the identified drugs were assessed in CIA mouse model.

Results: The first and second round drug library screening aimed to select out the drugs that could inhibit the proliferation of FLS. Results showed, from 1815 drugs, 372 drugs were identified at the initial screening (Figure 1A) and 121 drugs were identified from the second screening (Figure 1B). The third round screening was performed to screen the drugs that could inhibit TNFα-induced inflammation, and results showed that a total of 77 drugs could inhibit mRNA expression levels of both IL-6 and IL-8 by over 50%, and 64 drugs could suppress secretion levels of both IL-6 and IL-8 for more than 20% (Figure 1C-F). Then a total of 14 drugs that were not anti-cancer drugs were used to further confirm the inhibitory effect on the TNFα induced inflammation, and results showed only Agomelatine (AOM), Cinacalcet (CCC), Amlodipine (ALM), Simvastatin (SV), and Pindolol (PDL) could suppress mRNA expression and secretion levels of IL-6, IL-8 (Figure 1G-J). As highly proliferated FLS and inflammatory cytokines play a critical role in the pathology of rheumatoid arthritis (RA), we tested the treatment effect of AOM, CCC, ALM, SV, and PDL in the CIA mouse model. Results showed that AOM (5mg/kg), CCC (10mg/kg), and PDL (10mg/kg) had a trend to reduce the clinical score but did not reach statistical meaning while SV (10mg/kg) did not show any treatment effect. Whereas, AOM (10mg/kg) could effectively alleviate the swelling of the the joint, which was as effective as the positive control drug methotrexate (MTX) (Figure 1K).

Conclusion: Agomelatine indentified from the FDA approved drug library could inhibit FLS proliferation and TNFα induced inflammation, and was therapeutic against CIA mouse model.

POS0839 THE COMPARISON OF MALIGNANCY RISK BETWEEN JAK INHIBITORS AND TNF INHIBITORS IN MULTI-CENTER COHORT STUDY

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Safety

T. Uchida1,2, N. Iwamoto2, S. Fukui2,3, S. Morimoto2, T. Aramaki2, F. Shomura1, K. Aratake1, K. Eguchi1, Y. Ueki2, A. Kawakami2, 1Ureshino Medical Center, Rheumatology, Ureshino, Japan; 2Nagasaki University Graduate School of Biomedical Science, Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 3Nagasaki University Graduate School of Biomedical Sciences, General Medicine, Nagasaki, Japan; 4Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; 5Hakujukai Sasebo Chuo Hospital, Rheumatology, Nagasaki, Japan

Background: Ytterberg et al. demonstrated the concern about the incidence of malignancy during treatment with tofacitinib [1]. However, there is few published data of such adverse events in clinical settings.

Objectives: We aimed to compare the incidence of malignancies in RA patients treated with JAK inhibitors and TNF inhibitors in real-world settings.

Methods: We enrolled 499 RA patients treated with JAK inhibitors (tacitinib, n=192 or baricitinib, n=104) or TNF inhibitors (adalimumab, n=88 or etanercept, n=115). The standardized incidence ratio (SIR) of malignancies were determined using the general Japanese population. After adjusting the clinical characteristic imbalance by propensity score weighting, we compared the risk of malignancy between JAK inhibitors and TNF inhibitors using Cox proportional hazard models.

Results: Observational period was 961.9 patient-years (PY), and median observation period was 1.3 years. We identified 11 cases (3.7%) of malignancies in JAK inhibitors and 4 cases (2.0%) in TNF inhibitors. The SIR for overall malignancies were comparable with general population (0.94, 95%CI: 0.26–2.41), and the SIR in JAK inhibitors was higher than the general population but no significant difference (1.61/100PY, 95%CI: 0.80–2.88). The adjusted hazard ratio was 0.38 (95%CI: 0.09–1.55) between JAK inhibitors and TNF inhibitors in the risk of malignancies (Figure 1).

Acknowledgements: This study is supported by Sichuan Science and Technology Program (2021JDRDC0045 and 2021YFS0164), Post-doctoral Research and Development Fund of West China Hospital of Sichuan University (2019XBXH090), and National Natural Science Foundation of China (No. 82201985).
Disclosure of Interests: None Declared.
DOI: 10.1136/annrheumdis-2023-eular.147
Conclusion: We demonstrated that the incidence of malignancy in JAK inhibitors was numerically high but not significant compared with general population and TNF inhibitors.

POS0841\n
EFFECTIVENESS AND SAFETY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR TNF- THERAPY IN GERMANY. FINAL RESULTS FROM A POST-MARKETING OBSERVATIONAL STUDY

Keywords: Targeted synthetic drugs, Real-world evidence, Rheumatoid arthritis

BACKGROUND: The efficacy and safety of Upadacitinib (UPA), a selective Janus kinase inhibitor (JAKi) for treatment of rheumatoid arthritis (RA) have been reported in clinical trials [1]. The IL-6 signals via the JAK-STAT pathway. However, it is not known whether the CK elevation is due to JAKi alone or to IL-6 inhibitor (IL-6i) as well.

OBJECTIVES: The objective was to examine whether the CK elevation is specific to JAKi therapy or similar to IL-6i therapy by propensity score (PS)-matching.

METHODOLOGY: A multicenter database of JAKi (n=168) and IL-6i (n=113) treatment comparisons are presented as number of events per 100 patient-years, including those significantly negatively related were stage, class, mHAQ, eGFR, and PSL dosage.

Conclusion: CK elevation was greater with JAKi treatment at 4W and maintained until 24W than with IL-6i treatment in RA patients with adjustment for background characteristics. The CK elevation might be specific to JAKi treatment. The mechanism needs to be clarified in the future.

Conclusion: In a real-world setting, UPA demonstrated comparable effectiveness and safety in prior TNFi patients, ts/bDMARD-naive patients and the overall patient population.

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Epidemiology.

Background: Janus Kinase inhibitors (JAK) and biologic disease modifying anti-rheumatic drugs (bDMARDs) are routinely used in the management of rheumatoid arthritis (RA) patients for whom conventional (c)DMARDs have failed. The use of glucocorticoids after DMARD initiation and the influence of comedication on treatment persistence, used as a surrogate for treatment effectiveness, remains unknown.

Objectives: To assess glucocorticoids usage after treatment initiation and to compare the impact of comedication on the persistence of JAK and bDMARDs in Australian RA patients.

Methods: A retrospective observational study was conducted among 4,521 RA patients in the Australian Medicare Database (from 2011 to 2022), aged ≥18 and for whom a JAKI or bDMARDs were dispensed. A deidentified 10% sample of the database was taken as a random representation of RA patients in Australia. Kaplan-Meier analysis was used to calculate drug persistence rates, defined as the time from treatment initiation until the date of the last dose when there had not been a script dispensed for 6 months. Wilcoxon Singed Rank test was used to compare glucocorticoid dose changes from 1-year prior to 1 and 1 – 2 years after initiation of the DMARDs. Only patients who had persisted on DMARDs for 2 years were included for analysis. Log-rank test was used to compare time on a particular DMARDs treatment between the following sub-groups: (a) monotherapy; (b) combination MTX; and (c) combination cDMARDs.

Results: A total of 634 met the inclusion criteria for the glucocorticoids analyses, average dose of glucocorticoids decreased from 4.1 mg/day at 1 year prior to initiation of DMARD, to 2.9 mg/day and 2.0 mg/day at 1- and 1–2-years post-initiation, respectively (Figure 1). Daily dose changes were statistically significant for all RA DMARDs combined, tofacitinib and baricitinib combined (1–2 years post initiation only), TNFi, abatacept, and tocilizumab. The proportion of patients with a decrease in glucocorticoids dose from 1 year prior to 1 and 1–2 years after DMARD initiation was 56% and 70% for all ‘DMARDs’ (n=634), 35% and 52% for baricitinib (n=23), 58% and 63% for tocilizumab, 59% and 61% for abatacept (n=87), 65% and 78% for tocilizumab (n=148), and 62% and 70% for TNFi (n=387), respectively. For each drug individually, treatment persistence rates were higher in combination with MTX and in combination with other cDMARDs, compared to monotherapy (Table 1). Statistical significance was only reached when comparing baricitinib combined with cDMARD to monotherapy baricitinib (65% [p=0.04] vs 52%), tofacitinib combined with MTX and combined with other cDMARDs to monotherapy tofacitinib (56% [p=0.01] and 55% [p=0.01] vs 45% and 45%); and TNFi combined with MTX and combined with other cDMARDs to monotherapy TNFi (63% [p=0.0001] and 65% [p=0.0001] vs 43%).

Conclusion: This real-world data showed that among Australian RA patients glucocorticoids dosage decreased with JAKI and bDMARD use. When treatment was compared with MTX or other cDMARDs persistence rates were not sig. diff. when comparing upadacitinib, baricitinib and TNFi. Tofacitinib had similar persistence rates to TNFi.

Average daily glucocorticoids usage.
Results: Mean age, the proportion of females and disease duration were similar across all groups. Improvements in efficacy outcome measures were seen for all groups. Baseline (median interquartile range [IQR]) CDAI was highest (worst) in Group 5 (52 [48, 60]), followed by Group 1 (49 [44, 53]). Groups 1 and 3 showed a rapid reduction in CDAI in the first 6 months and sustained response over 12 months. Groups 2, 4 and 5 demonstrated slower response trajectories, with continued improvements in the proportion of CDAI responders between 6 and 12 months; of note, Group 5 constituted 16.8% (80/475) of the total analysis population. Table 1 shows that despite substantial and comparable improvements in CDAI components across all 5 groups over 12 months, Group 5 demonstrated some residual disease activity.

Conclusion: A group-based multivariate trajectory model identified 5 distinct CDAI disease activity trajectories in patients from FINCH 1 receiving FIL200. Patients in all groups demonstrated either fast and sustained response or slower and continued improvements, with no or low numbers of swollen or tender joints at Month 12. The current analysis suggests that patients who do not achieve CDAI LDA within 6 months may still benefit from treatment continuation and informs a range of expectations for times to clinical response. Future work will assess biomarker profiles that may be used to predict the observed clinical response patterns.

POS0843

DISTINCT TREATMENT RESPONSES IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING FILGOTINIB 200 MG OVER 12 MONTHS: A POST HOC ANALYSIS OF FINCH 1

Keywords: Remission, Rheumatoid arthritis

P. C. Taylor1, Y. Tanaka2, E. Aiello3, T. Debray4, C. Watson5, K. Harris6, G. R. Burmester7, 1Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; 2University of Occupational and Environmental Health, Kitakyushu, Japan; 3Cytel, Real-world Analytics, Toronto, Ontario, Canada; 4Galapagos NV, Biostatistics, Mechelen, Belgium; 5Galapagos Biotech Ltd, Medical Affairs, Cambridge, United Kingdom; 6Galapagos NV, Medical Affairs, Mechelen, Belgium; 7Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: FINCH 1 (NCT02885796) was a Phase 3 randomised controlled trial evaluating filgotinib (FIL) in patients with rheumatoid arthritis and an inadequate response to methotrexate (MTX).[1] Patients received background MTX and were randomized 3:3:2:3 to FIL 200 mg (FIL200), FIL 100 mg, adalimumab or placebo.

Objectives: To identify patterns of response trajectory over 12 months in patients from FINCH 1 receiving FIL200.

Methods: Group-based trajectory modeling is a statistical method which groups individuals based on similar patterns of change in an outcome over time.[2] A group-based trajectory modeling approach was applied to identify five distinct phenotypic groups in terms of observed clinical disease activity index (CDAI) outcomes (and components) over a 12-month period (Figure 1). Responders were recorded as either low disease activity (LDA) or remission, defined as CDAI between 2.9 and 10, or ≤2.8, respectively, at 6 or 12 months.

Table 1. Efficacy outcomes from baseline to Month 12 in phenotypic patient groups receiving FIL200: CDAI components.

Data are median (IQR) unless otherwise stated. abs, absolute; CDAI, clinical disease activity index; IQR, interquartile range; LDA, low disease activity; PhGADA, Physician’s Global Assessment of Disease Activity; PGADA, Patient’s Global Assessment of Disease Activity; SJC28, swollen joint count 28; TJC28, tender joint count 28.
Background: Filgotinib (FIL) is an oral Janus kinase 1 preferential inhibitor, approved for the treatment of moderate to severe active rheumatoid arthritis (RA). In previous analyses, comparable incidence of selected adverse events (AEs) occurred in FIL 200 mg (FIL200) and 100 mg (FIL100) dose groups, except for herpes zoster.[1]

Objectives: To provide an update on FIL selected AEs up to a median (max) exposure of 3.8 (8.3) years.

Methods: Integrated FIL RA data from 7 clinical trials are reported: phase 2 (NCT01888874, NCT01894516), phase 3 (NCT02889796, NCT02873936, NCT02886728), and the long-term extension studies DARWIN 3 phase 2 (NCT02065700) and FINCH 4 phase 3 (NCT03025308). Exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE), censored at time of first event, were determined for major adverse cardiovascular event (MACE), venous thromboembolism (ASTE), arterial systemic thromboembolism, non-melanoma skin cancer (NMSC), malignancies excluding NMSC, herpes zoster, serious infections and deaths. Data were as of May 2, 2022 (DARWIN 3) and May 6, 2022 (FINCH 4). MACE and VTE only include positively adjudicated events with confidence intervals overlapped between the dose groups.

Results: The as-treated population included 3691 patients with 12,541 PYE.

- **All-cause mortality**: 26 (1.6), FIL200; 21 (1.3), FIL100 (n=1647).
- **MACE**: 22 (1.3), 27 (1.2), 0.49 (0.3, 0.7), 0.34 (0.2, 0.5), FIL200 vs FIL100.
- **VTE**: 9 (0.5), 15 (0.7), 0.20 (0.1, 0.4), 0.19 (0.1, 0.3), FIL200 vs FIL100.
- **ASTE**: 1 (0.01), 1 (0.01), 0.02 (0.0, 0.1), 0.01 (0.0, 0.1), FIL200 vs FIL100.
- **NMSC**: 9 (0.5), 27 (1.2), 0.20 (0.1, 0.4), 0.34 (0.2, 0.5), FIL200 vs FIL100.
- **Malignancies**: 30 (1.8), 57 (2.5), 0.66 (0.4, 0.9), 0.71 (0.5, 0.9), FIL200 vs FIL100.
- **Herpes zoster**: 49 (2.9), 114 (5.0), 1.10 (0.8, 1.5), 1.48 (1.2, 1.8), FIL200 vs FIL100.
- **Serious infections**: 97 (5.9), 149 (6.6), 2.18 (1.8, 2.2), 1.86 (1.6, 2.2), FIL200 vs FIL100.

**Table 1. Frequencies and EAIRs of selected AEs in parent and ongoing long-term extension RA clinical trials**

**Figure. Event probability of serious infection and herpes zoster**

Conclusion: Over a maximum of 8.3 years, FIL200 and FIL100 continued to show small numerical differences in EAIRs of selected AEs between dose groups in the overall RA population. Slightly higher incidence rates for NMSC, herpes zoster and all-cause mortality were reported in the FIL200 than FIL100 group, with a higher incidence of MACE and serious infections with the lower dose; confidence intervals overlapped between the dose groups.

**EFFECTS OF NINTEDANIB ON CIRCULATING BIOMARKERS IN PATIENTS WITH PROGRESSIVE FIBROSING AUTOIMMUNE DISEASE-RELATED INTERSTITIAL LUNG DISEASES**

**Keywords:** Clinical trials, Lungs, Biomarkers

T. Maher1, F. Bonella2, S. Assassi3, I. Noth4, C. Diefenbach5, C. Ittrich6, K. Rohr7, M. Kolb8, National Heart and Lung Institute, Imperial College London, London, UK, and, Keck School of Medicine, University of Southern California, Los Angeles, California, United States of America; 9Ruhlandklinikum University Hospital, Duisburg-Essen University, Center for Interstitial and Rare Lung Diseases, Essen, Germany; 10University of Texas McGovern Medical School, Houston, Division of Rheumatology, Texas, United States of America; 11University of Virginia, Division of Pulmonary and Critical Care Medicine, Charlottesville, United States of America; 12Boehringer Ingelheim Pharma GmbH & Co. KG, Translational Medicine and Clinical Pharmacology, Biberach an der Riss, Germany; 13Boehringer Ingelheim Pharma GmbH & Co. KG, Global Biostatistics and Data Sciences, Biberach an der Riss, Germany; 14Boehringer Ingelheim International GmbH, TA Inflammation Medicine, Ingelheim am Rhein, Germany; 15McMaster University and St. Joseph's Healthcare, Division of Respiratory, Hamilton, United States of America

**Background:** Data from the randomised placebo-controlled INBUILD trial in subjects with progressive fibrosing interstitial lung diseases (ILDs) other than idiopathic pulmonary fibrosis suggested that nintedanib may have effects on circulating levels of biomarkers of epithelial injury, inflammation and extracellular matrix (ECM) turnover.

**Objectives:** We investigated the effects of nintedanib on circulating biomarkers in subjects in the INBUILD trial who had pulmonary fibrosis due to autoimmune disease.

**Methods:** Subjects in the INBUILD trial who had diffuse fibrosing ILD of >10% extent on HRCT and met criteria for progression of ILD within the prior 24 months, despite management in clinical practice. Subjects were randomised to receive nintedanib or placebo, stratified by fibrotic pattern on HRCT and met criteria for progression of ILD within the prior 24 months, despite management in clinical practice. Subjects were randomised to receive nintedanib or placebo, stratified by fibrotic pattern on HRCT (usual interstitial pneumonia-like fibrotic pattern or other fibrotic patterns). Blood samples were taken at baseline and at weeks 12, 24, 36 and 52. Fold changes in adjusted mean levels of biomarkers were analysed using a linear mixed model for repeated measures. Data were log10 transformed before analysis and estimates of change from baseline were back-transformed.

**Results:** Of 663 subjects, 170 had autoimmune disease-related ILDs; 82 of these subjects received nintedanib and 88 received placebo. Over 52 weeks, there were treatment-related decreases in fold changes from baseline in levels of Krebs von den Lungen-6 (KL-6), surfactant protein D (SP-D), CA-125 (markers of epithelial injury) in subjects who received nintedanib versus placebo (Figure 1). The most pronounced difference between nintedanib and placebo was in CA-125. The effect of nintedanib on CA-125 was observed as early as week 12. Small decreases in fold changes from baseline in soluble intercellular adhesion molecule (s-ICAM) (a marker of inflammation) and in CSM and pro-C6 (markers of ECM turnover) were observed in subjects who received nintedanib versus placebo (Figure 2). No notable trends were observed for the other biomarkers assessed.

**Conclusion:** In subjects with progressive fibrosing autoimmune disease-related ILDs, nintedanib reduced circulating levels of markers of epithelial injury, with the most pronounced effect observed on CA-125. The treatment-related decreases in these markers in subjects with autoimmune disease-related ILDs were similar to those observed in subjects with other ILDs.

**Acknowledgements:** The INBUILD trial was funded by Boehringer Ingelheim. Martin Kolb was a member of the INBUILD Steering Committee.

**EFFICACY, SAFETY, AND RECURRENCE OF IGURATIMOD COMBINED WITH CSDMARDS TREATMENT IN RHEUMATOID ARTHRITIS: A PROSPECTIVE REAL-WORLD STUDY**

**Keywords:** Disease-modifying drugs (DMARDs), Clinical trials, Rheumatoid arthritis

Q. Che1,2, X. Lu2, X. Gu1,2, Y. Li2, X. Zhang3, H. Wang4, Q. Shu5,6, Qilu Hospital, Cheelo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; 7Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Qilu Hospital, Jinan, China; 8Tianjin Medical University General Hospital, Department of Rheumatology, Tianjin, China; 9Yantaishan Hospital, Department of Rheumatology and Immunology, Yantai, China; 10Jiangsu Sincere Pharmaceutical Co., Ltd., Department of Marketing Management, Nanjing, China

**Background:** Iguardimod (IGU) is widely used in the treatment of rheumatoid arthritis (RA) and has been considered the first-line treatment option in many countries. The efficacy and safety of IGU combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) therapy have been...
confirmed by many studies [1]. Only a few studies focused on the long-term efficacy and safety of IGU treatment, and the maintenance strategy after short-term remission (REM) still needs to be explored.

**Objectives:** To observe the long-term efficacy, safety, and recurrence of IGU combination with csDMARDs in the treatment of active RA and the characteristics of patients who obtain the most benefit from IGU.

**Methods:** The study was conducted in China (ClinicalTrials.gov ID: NCT03855007), Patients who matched the 2010 ACR/EULAR RA criteria or the 2014 early rheumatoid arthritis (ERA) criteria [2] were recruited. According to patientsTrials.gov ID: NCT03855007, Patients who matched the 2010 ACR/EULAR RA criteria or the 2014 early rheumatoid arthritis (ERA) criteria eneniet from IGU on with convention follow-up from baseline to week 96 regularly. We divided them into three groups according to whether and when to reduce the drugs: maintained (MA), reducing the dose of IGU, MTX, and LEF after (AF) or before (BF) low disease activity (LDA), or REM was achieved. The proportion of LDA or REM of DAS28-ESR ≥ 0.6 [3], and the occurrence of adverse events (AE) were investigated. The chi-square test or long-rank test analyzed the corresponding statistical differences.

**Results:** A total of 246 patients were enrolled in this study, and 131 (53.3%) participants completed the 96-week follow-up. Efficacy analysis found that the proportion of achieving ACR20 reached a plateau after 24 weeks, while there was a sustained increase in the LDA and REM ratio of DAS28-ESR (week 24: 57.25% vs. week 96: 68.70%, p = 0.06), ACR50 (66.41% vs. 77.86%, p = 0.01) and ACR70 (22.90% vs. 41.98%, p < 0.01) (Figure 1 A, B). Further subgroup analysis revealed the expected effects of age, gender, and disease duration on whether achieved the LDA or REM at 96 weeks. Moreover, the time of IGU, MTX, and LEF reduction also played an essential role in long-term treatment. LDA or REM should be achieved before reducing the dose of IGU and csDMARDs, especially for the long-course, younger, with shorter morning stiffness RA patients. Patients were able to achieve and maintain LDA or REM and ACR50 responses better than the BE group (n=43) (Figure 1 C). There was no statistical difference in the incidence of AE between BE and AF groups (p = 0.44). During the follow-up period, 48 patients had a relapse of the disease in the AF and BE groups. The subgroup analysis found that drug reduction after REM was more recommended in patients with a diagnosis of RA (vs. ERA), disease duration ≥ 2 years, age < 45 years, and morning stiffness < 1 hour (Figure 1 D) for maintaining long-term LDA or REM (p < 0.05).

**Conclusion:** The RA patients could achieve deeper REM and sustained after long-term treatment of IGU combination with csDMARDs. LDA or REM should be achieved before reducing the dose of IGU and csDMARDs, especially for the long-course, younger, with shorter morning stiffness RA patients. IGU monotherapy was shown to be safe and effective in improving the signs and symptoms of moderate-to-severe RA through 84 weeks (wks) when administered as monotherapy in patients (pts) with a prior inadequate response to MTX in the phase 3 SELECT-MONOTHERAPY trial (NCT02706951).[1]

**Background:** Upadacitinib (UPA), an oral JAK inhibitor, was shown to be safe and effective in improving the signs and symptoms of moderate-to-severe RA through 84 weeks (wks) when administered as monotherapy in patients (pts) with a prior inadequate response to MTX in the phase 3 SELECT-MONOTHERAPY trial (NCT02706951).[1]

**Objectives:** To evaluate the efficacy and safety of UPA monotherapy up to wk 260 from the long-term extension (LTE) of SELECT-MONOTHERAPY.

**Methods:** Pts with active RA on stable MTX were randomly assigned to either continue MTX (cMTX) or switch to UPA monotherapy at 15 mg (UPA15) or 30 mg (UPA30) once daily (QD) during the 14-wk randomized, double-blind treatment period. From wk 14, the start of the LTE, pts receiving cMTX were switched to UPA15 or UPA30 per pre-specified assignment at baseline or 15 mg (UPA15) or 30 continued their initial treatment assignment. After the study protocol was amended (13 December 2019), all pts treated with UPA30 were eventually switched to UPA15 (approved dose). Efficacy outcomes through wk 260 are presented by randomized treatment group and reported as observed and using non-responder imputation. Safety results are presented based on actual treatment received with treatment-emergent adverse events (TEAEs) summarized per 100 pt years (PY) of exposure through a cut-off date of 10 August 2022, when all pts completed wk 260.

**Results:** Of 648 pts randomized, 299 (46%) discontinued the study drug by wk 260 primarily due to AEs (16%), consent withdrawal (12%), or other reasons (11%). At wk 260, pts on UPA maintained or further demonstrated clinical improvement across various endpoints; similar efficacy outcomes were also observed among pts who switched from cMTX to UPA15 or 30 (Table 1). As observed, over three-quarters of pts achieved low disease activity based on CDAI and DAS28-ESR at wk 260. Total PY of exposure were 1110.0 for UPA15, 812.5 for UPA30, and 300.2 for UPA15.
switched from UPA30. The most frequently reported TEAEs were urinary tract infection, creatine phosphokinase (CPK) elevation, upper respiratory tract infection, nasopharyngitis, bronchitis, and RA worsening/flare. COVID-19 pneumonia was the most common serious AE. Pts on UPA30 had higher rates of herpes zoster (HZ), hepatic disorder, neutropenia, lymphopenia, and CPK elevation than pts on UPA15; rates of serious infection and malignancy excluding non-melanoma skin cancer (NMSC) were similar between UPA doses (Figure 1). Most HZ events affected 1–2 dermatomes with 2 ophthalmic (UPA15: 0.2 E/100 PY) and 1 disseminated (UPA30: 0.1 E/100 PY) cases reported. Eleven adjudicated MACE (UPA15: 0.5 E/100 PY; UPA30: 0.7 E/100 PY) and 10 adjudicated VTE (UPA15: 0.6 E/100 PY; UPA30: 0.4 E/100 PY; UPA15 switched from UPA30: 0.3 E/100 PY) all occurred in pts with ≥1 cardiovascular risk factor. Through wk 260, 16 deaths were reported (10 treatment-emergent) with 5 related to COVID-19 infection.

Conclusion: UPA monotherapy continued to be effective in treating RA signs and symptoms through wk 260. No new safety signals were identified with longer-term exposure to UPA, consistent with prior findings[1–3] and the established safety profile of UPA across indications.

Background: Baricitinib (BARI), an oral selective JAK1/2 inhibitor, is approved for treating adults with moderate to severe active rheumatoid arthritis (RA). RA-BE-REAL is an ongoing 3-year, multinational, prospective, observational study of adult patients with RA starting BARI or any biologic or other targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD).

Objectives: To report treatment discontinuation and effectiveness in patients with RA receiving BARI or b/tsDMARD, based on prior b/tsDMARD use (experienced/naïve) and age <65 years versus ≥65 years, in Europe.

Disclosure of Interests: All authors declare no conflicts of interest.
Methods: Patients with RA initiating treatment with BARI 2 or 4 mg (cohort A) or any b/tsDMARD (cohort B) for the first time were included. The primary outcome is time to discontinuation (TTD) for any cause (excluding sustained response) at 2 years; TTD at 6 months has been published [1]. Discontinuation (Kaplan-Meier analyses and rates) and effectiveness (Clinical Disease Activity Index [CDAI] low disease activity [LDA] and remission rates) of treatment to 2 years, based on prior b/tsDMARD status (experienced/naïve) and age (<65/≥65 years) were analysed post-hoc and descriptively for cohort A and subgroups of cohort B.

Results: Key baseline characteristics of 1008 RA patients and effectiveness at 2 years for the subgroups in this analysis are shown in the Table 1. Numerically more BARI-treated patients were receiving monotherapy (Table 1). By 2 years, 31.1%, 54.7% and 47.6% of b/tsDMARD-naïve patients aged <65 years were 28.4%, 65.6% and 44.0%, b/tsDMARD experienced patients aged <65 years were 47.0%, 59.0% and 65.5% and b/tsDMARD experienced patients aged ≥65 years were 42.0%, 73.3% and 66.7%. An example of TTD is presented in the Figure 1. Consistent CDAI LDA and remission rates were observed with BARI regardless of age and prior treatment (Table 1).

Conclusion: Two-year discontinuation rates and effectiveness with BARI in a real-world setting were consistent irrespective of previous treatment or patient age.

* Effectiveness data were not available for all patients. **Mean standard deviation** n (%) R Vin (%). * An additional 65 patients in total received other tsDMARDS (7–23 per group); data for these patients are not shown because of the small numbers.
Results: Through 5 yrs, 1417 pts were exposed to UPA (4497 pt-ys) and 579 to ADA (1472 pt-ys). UPA was generally well tolerated, with similar rates of TEAEs, serious TEAEs, TEAEs leading to discontinuation of study drug, and COVID-related TEAEs vs ADA (Figure 1). Rates of most AEs of special interest with UPA were similar vs ADA, except for numerically higher rates of herpes zoster, creatine phosphokinase elevation, lymphopenia, and hepatic disorder (mainly transaminase elevations) with UPA. In the 651 and 327 pts originally randomized to UPA and ADA, respectively, greater proportions of pts achieved CDAI LDA and remission, and DAS28(CRP) scores ≤3.2 and ≥2.6, with UPA vs ADA (Table 1). Through 192 wks, similar proportions of pts treated with UPA vs ADA had no radiographic progression; mean changes from baseline in mTSS were similar, except for a numerically smaller change with continuous UPA (Table 1).

Conclusion: The safety profile of UPA over 5 yrs was consistent with the 3-yr results and the integrated phase 3 safety analysis.[1,2] Consistent with the 3-yr analyses,[2] UPA continued to show numerically better clinical responses than ADA at 5 yrs. Radiographic progression remained similarly low through 192 wks with UPA and ADA.

POS0850 THE EFFECT OF PERIOPERATIVE JANUS KINASE INHIBITOR WITHDRAWAL ON SURGICAL SITE INFECTION AND FLARE OF RHEUMATOID ARTHRITIS IN ORTHOPEDIC SURGERY: A MULTI-CENTER OBSERVATIONAL STUDY

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Targeted synthetic drugs

Background: To prevent surgical site infection (SSI), recent guidelines recommend a 3-day preoperative withdrawal of Janus kinase inhibitors (JAKi) in rheumatoid arthritis (RA) patients undergoing orthopedic surgery [1]. However, there is still insufficient evidence to support this practice. On the other hand, RA flare associated with JAKi withdrawal is also an important outcome, and an appropriate withdrawal period is crucial.

Objectives: We conducted a multicenter observational study to investigate the effect of the perioperative JAKi withdrawal period on SSI and RA flares in orthopedic surgery.

Methods: Patients with RA who visited the orthopedic surgical care centers between 2018 and 2021, and underwent JAKi before orthopedic surgery were included. We defined SSI based on the United States Centers for Disease Control criteria and flare as the clinician-assessed newly appearing or worsening joint pain or swelling during JAKi discontinuation.
Results: Of 30 patients, 23 (76.7%) patients withdrew JAKI. More than half of the patients withdrew JAKI 1 day before surgery or continued it (16/30, 53.3%). The median preoperative and postoperative JAKI withdrawal periods were 1 day (interquartile ranges [IQR]: 0–3.3) and 4.5 days (0.8–11.8), respectively. Two patients (6.7%) developed SSI. Both had multiple risk factors for SSI (Figure 1). Seven out of 30 patients flared (23.3%). The postoperative withdrawal period of JAKI was significantly associated with flares (odds ratio [OR] for > 14 vs. <7 days: 8.5, 95% confidence interval [CI]: 0.97–74.4, p = 0.048) (Table 1). The risk of RA flare increased by 15% for each postoperative withdrawal day of JAKI (OR [95% CI]: 1.15 [1.00–1.34], p = 0.01). Conversely, the preoperative withdrawal period was not associated with flare (OR for ≥ 4 vs. < 1 day: 3.25, 95% CI: 0.46–22.9, p = 0.24).

Conclusion: Real-world data showed the incidence of SSIs is low, despite the fact that a large percentage of patients have been withdrawn JAKI 1 day prior to surgery or continued it. Patients who developed SSI had multiple risk factors regardless of the perioperative JAKI withdrawal period. Considering the risk factors for SSI, shortening the postoperative JAKI withdrawal period may be essential to prevent RA flares.

Background: In the age of targeted-synthetic disease-modifying antirheumatic drugs (tsDMARDs), filgotinib represents the last JAK1 inhibitor available in Europe for rheumatoid arthritis (RA). Filgotinib is characterized by predominantly inhibition of JAK1 and its efficacy and safety have been highlighted by phase 2/3 studies, but no real-life data in RA are currently available.

Objectives: The aim of this study was to evaluate the effectiveness and safety profile of filgotinib in real-life setting in RA patients included in Italian GISEA (Group for the Study of Early Arthritis) registry.

Methods: For this study, data from RA patients treated with filgotinib recorded in Italian GISEA registry were analysed. Disease activity scores and patients reported outcomes (PROs) were compared at baseline and six months follow-up, using paired t-tests. The retention rate was estimated by the Kaplan-Meier method, while a cox regression model was used to search for possible factors influencing drug survival.

Results: One hundred and seventy-nine patients (female 89.4%, age 57.8±12 years, FR/ACPA+64.3%, current/former smoker 31.8%) included in GISEA registry started filgotinib for active RA. Most patients were taking filgotinib as second (23.5%) or further (43%) b/tsDMARDs line of treatment. Filgotinib was used in monotherapy in 66.5% of patients, while 52% were not on treatment with glucocorticoids (GCs) at baseline. All demographic and clinical data are reported in Table 1. A follow-up visit was available for 122 patients (mean time of first follow-up visit: 4±2 months). As shown in table 1, we observed a decrease of all disease activity scores and PROs. At first follow-up visit, 67.8% of patients were in remission/low disease activity according to CDAI and 65.4% according to SDAI. Kaplan-Meier analysis highlighted that drug persistence was similar either in monotherapy or combination therapy (Figure 1a), and irrespective of GCs at

Background: In the treatment of RA, JAK inhibitors are a valuable option to meet remission or low disease activity (LDA) treatment targets following an inadequate response (IR) or intolerance to ≥1 conventional synthetic disease-modifying anti-rheumatic drug (DMARD). Fil is a JAK1 preferential inhibitor available in two doses for the treatment of moderate to severe RA.

Objectives: To evaluate long-term efficacy of two doses of Fil in clinically relevant pt populations.

Methods: In this interim analysis, efficacy (non-responder imputation) of Fil 200mg (Fil200) and 100mg (Fil100) was assessed from LTE baseline (BL) to W156 in pts with an IR to methotrexate (MTX-IR) and biologics (bDMARD-IR), enrolled from FINCH 1 (NCT02889796) and 2 (NCT02873936) parent studies (PS), respectively, receiving ≥1 Fil dose in FINCH 4 (NCT03025308).

Results: Study design, BL characteristics and W48 outcomes for MTX-IR[2] and bDMARD-IR[6] pts were reported previously. For MTX-IR and bDMARD-IR pts who received Fil200 or Fil100 in the PS, W156 remission rates using Boolean 1.0 criteria were 20.5% and 15.8%, and 18.2% and 8.9%, respectively. Adopting the Boolean 2.0 criteria slightly increased remission rates for Fil200 and Fil100 at W156: +4.2% and +4.9% for MTX-IR pts, and +1.5% and +2.4% for bDMARD-IR pts, respectively. For pts rerandomized to Fil on entering the LTE, Boolean 2.0 criteria also increased remission rates vs Boolean 1.0. Both MTX-IR (Figure 1) and bDMARD-IR pts maintained long-term Boolean remission through W156 with Fil200 and Fil100, irrespective of prior Fil. Results for Disease Activity Score 28 with C-reactive protein (DAS28-CRP) ≤2.6, Clinical Disease Activity Index (CDAI) ≤2.8, and Simplified Disease Activity Index (SDAI) ≤3.3, and mean change from PS BL in Health Assessment Questionnaire–Disability Index (HAQ-DI) and pain are shown (Table 1). Similar trends in efficacy were seen for LDA and ACR response criteria.

Conclusion: In FINCH 4, both Fil200 and Fil100 showed sustained efficacy up to W156 in clinically relevant pt populations. Boolean 2.0 criteria classified more pts in remission, in line with the range reported in the validation study.[3]

**Drug Retention of Biologic and Targeted Synthetic DMARDs in Korean Seropositive Rheumatoid Arthritis (RA) Patients: A Real-World Single-Center Retrospective Study**

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, bDMARD

B. W. Lee, J. J. Lee, W. L. Kim, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Despite the approval of the new janus kinase inhibitors (JAKI) for rheumatoid arthritis (RA) treatment, the real world data on the drug effectiveness of biologic DMARDs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) including recently approved JAKI is scarce, especially in Asia.

Objectives: The purpose of this single center, retrospective study was to compare the short and long-term retention rates of b/tsDMARDs including recently approved JAKI in Korean seropositive RA patients.

Methods: This study was conducted with a total of 3,158 treatment courses of 1063 seropositive RA patients who started b/tsDMARDs between 2008 and 2020 at Seoul St. Mary’s Hospital [adalimumab (ADA; n = 332), etanercept (ETN; n = 369), infliximab (IFX; n = 146), abatacept (ABT; n = 152), tocilizumab (TCZ; n = 299), tofacitinib (TOF; n = 136), and baricitinib (BAR; n = 104)]. Discontinuation after 1 year and 3 years from the first prescription of each drug was investigated. Kaplan-Meier survival analysis of time to discontinuation was conducted to compare the difference in drug retention rate for each drug in b/tsDMARDs-naïve and experienced group, respectively. Patient-level predictors for drug discontinuation were evaluated by a Cox proportional hazard model.

Results: Overall 1-year drug retention rate was as follows: from 60.1% of ADA to 90.0% of TOF in the b/tsDMARDs-naïve group & from 55.2% of IFX to 84.8% of TOF in the b/tsDMARDs-experienced group. And 3-year drug retention rate was as follows: from 36.9% of IFX to 86.5% of TOF in the b/tsDMARDs-naïve group & from 31.0% of IFX to 65.4% of TCZ in the b/tsDMARDs-experienced group. The drug discontinuation seems to be affected by several factors including previous treatment history, starting year, and specific type of b/tsDMARDs, and baseline level of erythrocyte sedimentation rate.

Conclusion: Compared to before 2015, the overall drug retention rate of b/tsDMARDs increased in Korean seropositive RA patients. TCZ and JAKI are as widely used as tumor necrosis factor-alpha inhibitors, and they were less often discontinued at 1 year and 3 years from the first prescription. Especially, drug with the highest 3-year retention rate was TOF in b/tsDMARDs-naïve group, and TCZ in b/tsDMARDs-experienced group.

REFERENCE:

**Figure 1. 1 & 3-year retention rates of each drug in b/tsDMARDs naïve and experienced treatment courses with seropositive RA.**

Background: The treatment to adopt when (Interstitial Lung Disease)ILD is detected in Rheumatoid Arthritis (RA) patients has always been a matter of debate. The management and treatment of RA-ILD is challenging because there is still little information available on this topic, and the main literature comes from observational studies. No clinical trials have been dedicated to this topic, however its consideration is increasing in guidelines. There is relatively limited data on the use of JAKi in patients with RA-associated ILD.

Objectives: The aim of this multicenter retrospective study was to investigate the effectiveness and safety of the available JAKi in patients with RA-ILD.

Methods: We retrospectively analyzed patients with classified RA and RA-ILD undergoing JAKi in 6 Italian tertiary centres from April 2018 to June 2022. We included patients with at least 6 months of active therapy and one high-resolution chest tomography (HRCT) carried out within 3 months before the start of JAKi treatment. The HRCT was then compared to the most recent one carried out within 3 months before the last available follow-up appointment. We also kept track of the pulmonary function tests.

Results: We included 43 patients with RA-ILD, 23 males (53.48%) with median age (interquartile range, IQR) of 68.87 (61.46-75.78) treated with JAKi. Clinical and disease characteristics have been reported in Table 1. The median follow-up was 19.1 months (11.03–34.43). The forced vital capacity remained stable in 22/28 (78.57%) patients, improved in 3/28 (10.71%) and worsened in 3/28 (10.71%). The diffusing Capacity of Lung for Carbon Monoxide showed a similar trend, remaining stable in 18/25 (72%) patients, improving in 2/25 (8%) and worsening in 5/25 (20%). The HRCT remained stable in 37/43 (86.05) cases, worsened in 4/43 (9.30%) and improved in the last 2 (4.65%) (Figure 1).

Background: Janus kinase inhibitors (JAKi) have been licensed for the treatment of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) and currently there is limited evidence of differences among the four available molecules while real-world data are needed for safety and efficacy.

Objectives: To investigate the efficacy and safety of approved JAKi and analyze the relationship between the patients’ baseline characteristics and drug survival.

Methods: This is a retrospective study on patients treated in 2021-2022 with tofacitinib, baricitinib, upadacitinib, or filgotinib for RA or with tofacitinib, baricitinib, or upadacitinib for PsA as first or subsequent line of therapy after the failure of one or more conventional DMARD. We collected demographic and clinical data including clinimetric indices and registered the presence of comorbidities, smoking, and previous DMARDs.

Results: The study included 205 patients (81% women) who started or continued a JAKi for RA or PsA between January 2021 and October 2022 (Table 1) and were followed until the cutoff on October 31, 2022 for a median of 24 (interquartile range 12-40) months for a total observation of 431 patients-years. One hundred-two (50%) patients received the JAKi as first-line treatment and 108 (53%) as monotherapy. At the last available observation, 144 (72%) patients still on JAKi, 27% with 54 (20%) reporting a temporary discontinuation of the therapy, in 69% of cases due to bacterial or viral infections of the upper respiratory tract. Forty-one (20%) patients stopped the JAKi for inefficacy, in 18 (44%) being a primary failure. Eighteen serious adverse events were registered at univariate analysis in bio-naïve patients (p=0.002) but none required the discontinuation of the JAKi. Better retention rates were observed in patients treated with JAK1i (73.6%), oJAKi (63.6%) and oMOA (54.7%) compared to TNFi (67.3%), oJAKi (63.6%) and oMOA (54.7%) with respect to JAK1i. Multivariate analysis confirmed that receiving JAK1i as monotherapy (p=0.04, odds ratio 2.01, 95% confidence interval 1.03-3.94) is associated with a longer treatment duration, opposite to having failed one bDMARD before receiving a JAKi (p=0.001, odds ratio 0.29, 95% confidence interval 0.14-0.6), irrespective of gender, age, and disease duration. Having RA or PsA did not impact the treatment duration.

Conclusion: Irrespective of the diagnosis of RA or PsA, JAKi cumulatively have the best treatment duration when used as monotherapy or as first line before a bDMARD. The safety and efficacy profiles did not differ significantly between RA and PsA, albeit a limited number of patients were included in the latter group.

Conclusion: Our study highlighted good effectiveness and safety of new and old b/tsDMARDs in Apulian cohort of RA patients included in BIOPURE registry. Of note, despite more than half patients starting JAKi or oJAKi who were multi-failure, they showed a similar drug survival compared to those on TNFi who were predominantly biologic-naive.

Background: JAK inhibitors (JAKi) are a new class of drugs developed for the treatment of different immune-mediated inflammatory diseases (IMIDs). Thrombotic events have been reported in some long-term extension studies as adverse effects. As a consequence, in 2017 the Food and Drug Administration (FDA) inserted a black box warning in the Summary of Product Characteristics (SPC) for Baricitinib, stating that it should be used with caution in patients at increased risk of thrombosis [1]. A similar warning was issued by the European Medicines Agency (EMA) in 2019 for Tofacitinib [2].

Methods: RCTs on the efficacy and safety of JAKi in IMIDs patients were identified by electronic search of the MEDLINE and EMBASE database until October 2022. Risk of bias was assessed according to Cochrane criteria. All JAKi and all IMIDs were included in the main analysis. Venous and arterial TE events (deep vein thrombosis, pulmonary embolism, unusual site thrombosis, superficial venous thrombosis, stroke, transient ischemic attack, coronary ischaemic events and peripheral artery ischaemia) and major adverse cardiac events have been reported from the safety analysis of the different RCTs. Studies which did not report any information on the cardiovascular safety profile in the paper or supplementary materials were excluded. Differences in thrombotic outcomes among groups were expressed as pooled odds ratios (OR). Owing to the limited number of studies, we did not perform a meta-regression analysis. The meta-analysis was calculated using the fixed-effect model.

Results: One phase I, 21 phase II, 3 phase II-III and 36 phase III RCTs on Rheumatoid Arthritis (32.8%), Atopic Dermatitis (22.9%), Psoriasis (11.5%), Inflammatory Bowel Disease (11.5%), Psoriatic Arthritis (9.8%), Ankylosing Spondylitis (6.6%) and Lupus Erythematosus (4.9%) were included, for a total of 19,443 patients in the JAKi group (Abrocitinib, Baricitinib, Brepocitinib, Deucravacitinib, Filgotinib, Ivarmacitinib, Peficitinib, Tofacitinib and Upadacitinib) and 9,073 in the placebo group. Thirty-one (unweighted rate 0.16%) TE events were reported in the JAKi group and 20 (unweighted rate 0.22%) in the control group in an unweighted mean follow-up of 16.8 weeks. IMIDs patients treated with JAKi had an increased TE risk compared to IMIDs patients treated with placebo (OR 0.69 [95% CI, 0.44–1.10, I² 0%] at fixed-effect model) (Figure 1). No clinically relevant results were seen among different IMIDs and drugs. The ORs of venous and arterial TE events were respectively 0.61 (95% CI, 0.32–1.15, I² 0%) and 0.78 (95% CI, 0.41–1.48, I² 0%) at fixed-effect model. The incidence of MACE in an unweighted mean follow-up of 16.8 weeks was 0.78 (95% CI, 0.41–1.48, I² 0%) at fixed-effect model.

Conclusion: Despite our study has some limits like the short duration of the RCTs, the different inclusion criteria, permitted concomitant therapies, mean age and mean disease activity, we did not find any evidence that JAKi increase the risk of venous and arterial TE events and MACE. The performed sub-analysis did not find any correlation between the use of any JAKi and TE events in any considered IMID, even if the meta-analysis is likely underpowered (i.e. I² > 50%) to highlight statistically significant differences of the incidence of TE events between different diseases and different JAKi. JAKi do not increase TE risk compared to placebo in IMIDs patients enrolled in phase II/III RCTs.

Results: JAKI were administered to 347 patients for an average of 64.5 weeks. There were 75 cases (21.6%) who discontinued the JAKI due to insufficient effect. Of the cases in which JAKI were discontinued, 45 (60.0%) were in the bDMARD switcher group, 22 (29.3%) were in the JAK cycler group, and 8 (10.7%) were switched to csDMARD alone. The continuation rate of the next treatment in the bDMARD switcher group and the JAK cycler group was 77.8% and 89.0% at week 12, respectively, with no significant difference (Log-rank p=0.2806). The CDAI improvement rates in swticher group and the JAK cycler group were 43.5% and 46.2%, respectively, at week 12, with no significant difference (Wilcoxon p=0.697). There was no significant difference in the CDAI improvement rate according to the treatment class and the number of b/tsDMARDs between the two groups (p>0.05). CDAI improvement rate with each of following b/tsDMARDs were TNFi=48.2%, IL-6i=30.0%, abatacept=42.4%, JAKi=49.9%. Especially for IL-6 inhibitors, 50.2% CDAI improvement rate was obtained when sarilumab was selected as the following DMARD.

Conclusion: JAK cycler, as well as bDMARD switcher, may be useful as the next treatment for patients who discontinue JAKI.

POS0861

EFFECT OF JAK1 INHIBITION ON EROSION REPAIR IN RHEUMATOID ARTHRITIS: A PILOT HR-PQCT STUDY

Keywords: Targeted synthetic drugs

H. So1, I. T. Cheng1, M. Li1, C. K. Wong2, L. S. Tam1. 1The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); 2The Chinese University of Hong Kong, Chemical Pathology, Hong Kong, Hong Kong (SAR)

Background: Blockade of JAK, preferably JAK1, by upadacitinib is a feasible approach to achieve erosion repair as it 1) is approved for the treatment of rheumatoid arthritis (RA), 2) effectively controls the inflammation and 3) targets pathogenic pathways responsible for bone homeostasis in the joint.

Objectives: To evaluate whether inhibition of JAK1 could lead to erosion repair on high-resolution peripheral quantitative computer tomography (HR-pQCT) in patients with active RA.

Methods: This was a 24-week, single-centered, prospective, non-randomized pilot study. We enrolled 20 adult patients with active RA (Disease activity score 28-C-reactive protein [DAS28- CRP] > 3.2) and ≥1 bone erosion on HR-pQCT. They were given upadacitinib 15mg once daily for 6 months. HR-pQCT of the 2-4 metacarpophalangeal (MCP) head was done at baseline and 6 months. The serum inflammatory cytokine profile and bone-cartilage interface biomarkers were also checked before and after treatment. The primary outcome was the change of erosion volume on HR-pQCT. Secondary outcomes included change in RA disease activity and serum biomarkers, as well as predictors of response to treatment. Erosion regression was defined as decrease in volume exceeding the smallest detectable change.

Results: The baseline clinical characteristics of the recruited patients were shown in Table 1. Of the 20 patients, 11 (55%) patients failed to respond to 3 or more csDMARDs. At 24-week, there was significant improvement in mean DAS28 (-1.75, p<0.001). Erosion regression was seen in 8 (40%) patients on HR-pQCT. Although no significant change in overall median erosion volume before and after upadacitinib (0.07 [-0.90 to 0.68 mm³] mm³, p=0.904) was noted, the deterioration was less obvious compared to a historic cohort of 20 patients with similar age and disease activity on csDMARDs (median erosion volume change in 6 months: 0.67 mm³). There was significant reduction in the serum level of bone resorption marker C1M before and after treatment, which was not seen in the historic cohort. Significant reduction in various inflammatory cytokines (e.g. TNF-α, IL-6) was also noted after treatment. When patients were stratified according to whether or not they had failed multiple csDMARDs, significantly high proportion of patients in the non-multiple-DMARDs failure group had volume regression in at least one erosion compared to those in the failure group (75% vs 25%, p=0.04). There was improvement in mean total erosion volume in the non-failure group (-0.33 ± 1.33 mm³), whereas mean erosion volume in the failure group worsened (2.09 ± 7.62 mm³). One patient developed chest infection requiring hospitalization and withdrew from the study. No other serious adverse event was noted.

Conclusion: The results of the study suggested upadacitinib was clinically efficacious in refractory RA disease and could retard erosion progression. Regression of erosion was possible, particularly in those with limited csDMARDs exposure. Whether earlier JAK1 inhibition could lead to better structural outcome warrants further investigations.

Background: Since 2018, JAK inhibitors became available in Italy for the treatment of adult patients with moderately to severely active Rheumatoid Arthritis (RA) and an inadequate response to methotrexate (MTX).

Objectives: This analysis aimed to characterize the prescription pattern of JAK inhibitors in patients with RA over the last 5 years.
Methods: Patient demographics, disease characteristics and medication history were collected. Patients starting treatment either with biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) or targeted synthetic (ts)DMARDs (baricitinib, tofacitinib, upadacitinib and filgotinib) were included in the analysis. Data were extracted from the GISEA (Gruppo Italiano di Studio sull’Early Arthritis) registry.

Results: From January 2018 to December 2022 overall 4424 patients with RA were included in the GISEA registry (3622 F: 802 M, mean age 57.9±12.8 years, mean disease duration 12.9±9.8 years). Overall, the number of patients starting bDMARDs and tsDMARDs in 2018, 2019, 2020, 2021 and 2022 was 725, 784, 1204, 794 and 913, respectively; 306 (42%), 319 (40.7%), 278 (23%), 291 (36.6%) and 335 (36.7%) started a JAK inhibitor. Figure 1 summarizes the prescription pattern of bDMARDs and tsDMARDs during the 5 years of observation (A) and the percentage of patients starting each JAK inhibitor (B). The prescription of JAK inhibitors was stable from 2018 to 2022 with the only exception of 2020 (coinciding with the beginning of the pandemic) when we recorded a significant decrease in JAK inhibitors prescribed (p<0.00001 vs 2019) and a significant increase in the number of patients treated with abatacept (from 12.1% to 17.1%, p=0.0024) and anti-IL-6R (from 16.3% to 23.7%, p=0.000067). Conversely, in 2021 the number of patients who started JAK inhibitors significantly increased (0.0<0.00001 vs 2020) and those starting anti-IL-6R significantly decreased (from 23.7% to 13.4%). From 2018 to 2022 the percentage of bDMARD-naive patients increased without reaching a statistical significance, from 30.7%, 36%, 43.5%, 44.4%, 40.3% of patients starting a JAK inhibitor after MTX-failure (Figure 1C).

Conclusion: The use of JAK inhibitors for treating RA of patients in Italy is stable from 2018 onward with a shift towards an earlier line of treatment and a significant change in the prescription pattern within the class over time.

POS0863 BARISUR STUDY: DESCRIPTIVE STUDY OF BARICITINIB SAFETY IN SPANISH PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Safety, Rheumatoid arthritis, Descriptive studies

E. Rubio Romero1, A. Gallego2, M. Llanes3, E. Delgado Vidal4, 5SevilleHospital Universitario Virgen del Rocio, Rheumatology, Seville, Spain; 4Hospital Universitario Badajoz, Rheumatology, Badajoz, Spain; 5Hospital Universitario Juan Ramón Jiménez, Rheumatology, Huelva, Spain; 4Seville, Rheumatology, Seville, Spain

Background: Baricitinib (BCT) and tofacitinib (TFC) are the most widely used JAK inhibitors worldwide and both were approved in Spain in 2017. Data from Oral Surveillance study showed in 2021 an increased risk of malignancies and major adverse cardiovascular events (MACES) in patients treated with TFC versus anti-TNF drugs. However, there is no clear position among rheumatologists regarding the risk of MACE, thromboembolic events (TEE) or other safety concerns of JAK inhibitors. Although JAK inhibitors have a common mechanism of action, each drug has specificities such as selective affinity to different targets, pharmacodynamics, metabolism and dosing, conferring differences between drugs. Therefore, it is to be expected that the safety profile may be different.

Objectives: The aim of this study is to collect real world data from Spanish patients to analyze efficacy trends, daily use patterns and a descriptive analysis of the safety profile of rheumatoid arthritis treatments in southern Spain.

Methods: A multicenter, observational, retrospective study was conducted, collecting data from patients with rheumatoid arthritis previously treated with methotrexate (MTX) and other prior biologic therapies.

Results: Data from 270 patients were analyzed, 73% were female, the mean age was 58 years (SD: 12.7) and the mean age at diagnosis was 47 years (SD:14.33). Of the population, 95.1% had some risk factor for MACE or TEE; specifically 75% had previous cardiac events, 2.6% and 9.4% had previous TEE and malignancies, respectively. The distribution of baseline treatment is shown in the Table 1. Median use of prior disease-modifying treatments (DMT) was 1 for the total population, but 2 for BCT patients. BCT patients had 10.5 (SD: 9.0) mean years of disease progression and initiated treatment at 57 (SD: 12.25) years mean age. After the first 12 months of follow-up, there was a trend towards reduce the use of NSAIDs (28.9% to 24.2%), prednisone 85% to 58.4%) and MTX (46.2% to 36.6%). Simultaneously, Disease Activity Score 28 (DAS28), VSG and PCR also decreased during the period from 4.92 (SD:0.84), 24.41 (SD: 15.78) mm/h and 11.89 (SD:9.69) mg/l to 3.06 (SD: 1.13), 20.79 (SD: 13.31) mm/h, and 8.21 (SD: 9.14) mg/l respectively. BCT safety profile was well tolerated, with 33 adverse events at 6 months of follow-up and 3 serious adverse events (TEE, pneumonia and stroke) during the period. Of BCT population, 576% stopped treatment due to toxicity or lack of efficacy.

Conclusion: Taking into account the heterogenicity and the age of our population, these preliminary results showed low risk of MACE and cancers with BCT for the Spanish cohort. Future analysis is guarantee in order to understand the safety profile in the long term.

POS0864 EFFECTIVENESS OF ANTIFIBROTICS IN RHEUMATOID ARTHRITIS-INTERSTITIAL LUNG DISEASE. NATIONAL MULTICENTER STUDY OF 50 PATIENTS IN CLINICAL PRACTICE

Keywords: Lungs, Rheumatoid arthritis, Descriptive studies
Background: Idiopathic lung disease (ILD) is a severe complication of rheumatoid arthritis (RA). Abatacept and rituximab are the preferred disease-modifying antirheumatic drugs (DMARDs) for RA-ILD [1-4]. However, progression of ILD despite its use is not uncommon. A subgroup analysis of the INBUILD trial has shown a slower decline in forced vital capacity (FVC) in patients with progressive fibrosing autoimmune disease-related ILDs with the antifibrotic nintedanib (NINTE) [5].

Objectives: A) To assess the efficacy of antifibrotic drugs, NINTE and pirfenidone (PIRFE), in Spanish RA-ILD patients with a progressive phenotype in clinical practice. B) To compare the profile of clinical practice RA-ILD patients with the RA-ILD patients included in the INBUILD trial [5].

Methods: National multicenter study of RA-ILD patients to whom NINTE or PIRFE were added due to progressive fibrosing ILD. Demographic and clinical variables were collected from all patients included. These features were compared with those of RA-ILD patients included in the INBUILD trial (n=89, 42 treated with NINTE and 47 with placebo). Forced vital capacity (FVC) evolution was the primary endpoint. Results are expressed as percentage, mean±SD or median [IQR].

Results: A total of 50 patients (19 women/31 men) from clinical practice were collected (NINTE=45, PIRFE=5), mean age 70±8 years. Median ILD duration up to antifibrotic initiation was of 45 [19-72] months. Mean FVC one year before antifibrotic start was 81±20 % predicted, whereas mean baseline FVC was 72±23 % predicted. Comparison of baseline characteristics of RA-ILD patients treated with NINTE in clinical practice (n=45) and RA-ILD patients of the INBUILD trial is shown in Table 1. The evolution of FVC and DLCO in our patients from the previous year of antifibrotic initiation is shown in Figure 1. After a median follow-up of 16 [5-24] months, no decline in mean FVC and DLCO values was observed. Stabilization or improvement of dyspnea was found in 83% of patients. NINTE was withdrawn in 8 patients due to: gastrointestinal adverse events (GAE) (n=6), death (n=1) or hemorrhage risk (n=1). PIRFE was withdrawn in 2 patients due to GAE.

Conclusion: Antifibrotics, specially NINTE, seem to slow ILD progression in patients with RA-ILD. In clinical practice, patients are treated later in the evolution of the disease, but results are satisfactory. Combination of antifibrotics and DMARDs in RA-ILD is possible and safe.

POS0865 THE CORRELATION BETWEEN FOUR ADHERENCE MEASUREMENTS METHODS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING METHOTREXATE

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

R. Hebing 1,2, N. Elhendry 3, E. Van Geel 1, M. Van Heuckelum 3, M. T. Nurmoohamed 1,2, B. Van den Berst 1,2, Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center, Amsterdam UMC location VUMc, Amsterdam, Netherlands; 3Sint Maartenskliniek, Department of Pharmacy, Nijmegen, Netherlands; 4Radioudumc, Department of Pharmacy, Nijmegen, Netherlands.

Background: Methotrexate (MTX) is the cornerstone in the pharmacological treatment of rheumatoid arthritis (RA) patients. However, medication adherence to MTX is not ideal, which might lead to suboptimal treatment outcomes. Consequently, instruments to assess medication non-adherence are warranted to detect and intervene on non-adherence. To date there is no consensus on the best method to determine adherence to MTX.

Objectives: The aim of this study was to assess the correlation between compliance measured with MEMS (gold standard) versus pill count, MTX-polyglutamate (PG) concentration and Compliance Questionnaire Rheumatology (CQR) in patients with established RA. Second, correlations between these methods and the Disease Activity Scores of 28 joints (DAS28) were examined.

Methods: Adult patients with established RA treated with MTX were included. Multivariable linear and logistic regression were used, with taking compliance assessed with MEMS as dependent variable versus pill count, MTX-PG concentrations, CQR, as independent variables, and DAS28 score versus each of the 4 adherence measurements methods. Medication, age and use of corticosteroids and NSAIDs were included as covariates in the analysis.

Results: 190 consecutive RA patients were included. Median follow-up time was 4.9 months ([IQR 3.6 – 6.2]). Pill count correlated with taking compliance assessed with MEMS (linear regression, β = .690, p < .001), whereas MTX-PG concentrations and CQR were not. Logistic regression only confirmed the correlation between dichotomized taking compliance MEMS and pill count (β = 5.64,
were: age, way of living status (e.g., alone, with a partner), educational level, biological-use, were included in the final model: age, treatment centre, amount of other medication, corticosteroid-use, LN transformed; CQR: Compliance Questionnaire Rheumatology; IV: independent variable; Missing data was imputed with 50 imputations. POS0666 OIL AND NUTS IN RHEUMATOID ARTHRITIS DISEASE ACTIVITY

Keywords: Rheumatoid arthritis, Diet and nutrition

S. Cavalli1,2, V. Edefonti3, M. Ferraroni3, R. De Vito4, F. Fiori5, M. Parpinel6, F. Ingegnoli1,2, R. Caporali1,2, 1University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 2ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; 3University of Milan, Branch of Medical Statistics, Biometry, and Epidemiology; 4University of Milan, Faculty of Medicine—DAME, Udine, Italy; 5University of Udine, Department of Medicine—DAME, Udine, Italy

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune arthropathy affecting around 1% of the general population. Though the availability of many synthetic and biologic DMARDs (disease modifying anti-rheumatic drugs), a non-negligible portion of patients still does not reach the remission. Increasing interest is raising about dietary interventions, in order to optimize disease control: scientific literature suggests that Mediterranean diet could exert an anti-inflammatory role in many rheumatologic conditions, including RA.

Objectives: In this cross-sectional analysis of RA patients from Italy, where extra virgin olive oil is traditionally used, we aim to assess if consumption of two food groups, olive oil and nuts, representing vegetable sources of fatty acids. Disease activity was measured with Disease Activity Score on 28 joints (DAS28-CRP) and the Simplified Disease Activity Index (SDAI). Robust linear and logistic regression models included tertile-based consumption categories of each food group and several confounders. Stratified analyses were performed by disease severity or duration.

Results: Higher consumption of both food groups exerted a beneficial effect on disease activity, significant only for olive oil (Beta: -0.33, p-value: 0.03) in the linear regression on the overall sample. This effect was stronger in the more severe or long-standing forms of RA (p-value for heterogeneity<0.05, especially for disease severity). Significant ORs were as low as −0.30 for both food groups, strata, and disease activity. Mean DAS28 significantly decreased by −0.70 for olive oil and −0.55 for nuts in the two strata; mean SDAI significantly decreased by 3.30 or more for olive oil in the two strata.

Conclusion: In this cross-sectional study on Italian RA patients, higher consumption of olive oil and nuts generally led to an improvement of disease activity, but, in most cases, the absence of statistical significance. The beneficial effect was, however, stronger for those patients with a more severe RA form or a long-standing RA activity, in the presence of significant heterogeneity across strata, especially for disease severity.

Psoriatic arthritis - clinical aspects (other than treatment)

B-CELL SUBSETS IN PERIPHERAL BLOOD ACROSS DISEASE PHASES OF PSORIATIC ARTHRITIS AND THEIR CORRELATION WITH SYNOVIAL TISSUE FEATURES

Keywords: Synovium, Biomarkers, Remission

D. Bruno1,2, B. Tolusso2, C. Di Mario2, S. Perniola2, D. Somma4, L. Petricca4, A. Chiricozzi1, M. R. Gigante1, A. Damore1, M. Kurowska-Sołtanska2, S. Allervinsky2, E. Gremese3,4,5,6, University of Verona, Department of Medicine, Verona, Italy; 2Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Division of Clinical Immunology, Rome, Italy; 3Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Division of Rheumatology, Rome, Italy; 4Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Division of Dermatology, Rome, Italy; 5Università Cattolica del Sacro Cuore, Division of Dermatology, Rome, Italy; 6Università Cattolica del Sacro Cuore, Division of Clinical Immunology, Rome, Italy

Background: Psoriatic Arthritis (PsA) has been historically considered as a T-cell driven disease, with the role of B-cells generally under investigated since common seronegativity. However, over the years new insights have come to light on B-cells in PsA, focusing on the presence of ectopic lymphoid structures as well as on the presence of specific anti-carbamylated/citrullinated cathelicidin LL37 antibodies in psoriatic SF and plasma.

Objectives: The aim of the study was to examine the frequencies of distinct peripheral blood (PB) B-cell subsets in across different disease phases, evaluating their potential correlation with synovial tissue (ST) heterogeneity in terms of inflammatory degree and microarchitectural organization.

Methods: 150 patients fulfilling the CASPAR criteria for PsA were recruited (81 naive to cDMARDs or bDMARDs, 45 c- and/or bDMARDs resistant and 24 in clinical and US sustained remission, respectively) and underwent US-guided ST biopsy and PB withdrawal. 22 patients with psoriasis (PsO) and arthralgia were included as comparison group. All ST FFPE specimens were routinely processed, stained with H&E and subjected to immunohistochemistry, blinded to clinical characteristics, using a H&E based semiquantitative score (KSS) integrated with the presence/absence of lymphocytes, plasmacells, granulocytes and myeloid degeneration, respectively. 1) Frequencies of PB B-cell subsets were determined by FACS using the CD27/17/CD20 classification as follows: naive B-cells (CD27+/CD20+/IgM-; IgM), memory (CD27+/CD20-/IgM-; IgM), switched memory (CD27+/CD20-/IgD-; IgD), late memory (CD27-/CD20+/IgD+; IgD+) and plasmacells (CD138+).

Results: In PsA cohort, the distribution of synovitis score was significantly different among patients with distinct disease phases (ANOVAs p<0.001). In particular, KSS was contingent on disease phase being significantly lower in PsA in remission (2.04 ± 1.39) compared to naive (3.20 ± 1.77, p=0.02) and resistant PsA (3.78 ± 2.22, p=0.001), while there was no significant difference between remission PsA and at risk PsO group in terms of synovial hyperplasia, stromal density, and lymphocyte infiltrate respectively. ST of c- and/or b-DMARDs resistant PsA was enriched of plasmacells than remission PsA (p=0.03). Considering B-cell subpopulations, PB of c- and/or b-DMARDs resistant PsA was enriched of plasmablasts and plasmacells compared to PsO at risk of PsA development (p<0.001 for plasmablasts and p=0.001 for plasmacells, respectively). Conversely, c- and/or b-DMARDs resistant PsA showed, at PB level, lower rates of switched memory and naive B-cells compared to PsO at risk of PsA development (p=0.02 for switched memory and p=0.03 for naive, respectively). Finally, stratifying PsA based on KSS category, remission PsA with persistent high grade synovitis (KSS > 5) showed lower rates of PB plasmablasts compared to remission PsA with low grade or without residual synovial inflammation (p=0.045).

Conclusion: Disease state across PsA course significantly impacts PB B-cell subsets distribution mirroring ST residual inflammation at the time of sustained disease remission and supporting the tight dynamic connection between PB and ST environments.

PSOS0688

NOT ALL SYNDENOMPHYES ARE EQUAL: THE IMPACT OF BODY MASS INDEX ON THE PRESENCE, LOCATION AND TYPE OF SYNDENOMPHYES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Comorbidities, Imaging

S. B. Ackigoz1, U. Gazeli2, S. Bakiro1, G. Ayan1, D. Solmaz1, E. Hepworth2, S. Aydin1, 1University of Ottawa, Rheumatology, Ottawa, Canada

Background: New bone formation is a hallmark of Axial spondyloarthritis (axSpA). Body mass index (BMI) is associated with the presence of syndenomphytes, especially in males. To date, it is not clear whether obesity impacts the axSpA through adipokines or biomechanical forces.

Objectives: We aimed to investigate the relation between BMI and the presence and types of syndenomphytes at different spine levels, to better understand the impact of biomechanical forces in AxSpA.

Methods: AxSpA patients who had cervical and lumbar spine x-rays as their standard of care were included (n=144). The cervical and lumbar spine x-rays were scored separately, for the presence and type (thin vs bulky) of syndenomphytes. The factors associated with syndenomphytes were investigated, using a multivariate logistic regression.

Results: The mean±SD age of the patients was 45.2±14.0. Syndenomphytes were seen in 48 (33.3%) patients of the cervical and 43 (29.9%) of the lumbar spine. Older and male patients had more frequent syndenomphytes on both levels. While the BMIs of patients with lumbar syndenomphytes were higher than those without (28.4 (8.2) vs 26.8 (7.0), p=0.015), patients with and without cervical syndenomphytes had similar BMIs (27.1 (8.3) vs 28.2 (7.5), p=0.177). Patients with cervical syndenomphytes had higher frequency of uveitis (47.9% vs 20.8%, p=0.001) than those without, which could not be detected for lumbar syndenomphytes. In regression analysis, age and male gender were associated with syndenomphytes in both the cervical and lumbar spine, whereas uveitis was associated only with syndenomphytes in the cervical spine (Table 1). BMI was associated only with syndenomphytes in lumbar spine, but not the cervical spine. The only factor that was found to be associated with bulky (vs thin) syndenomphytes was BMI for the lumbar spine, but not for the cervical spine (Table 1). Presence of PsA was not linked to the bulky type syndenomphytes.

Conclusion: Higher BMI increases the risk of syndenomphytes in the lumbar spine as well as impacting its shape; but not in the cervical spine. Abdominal obesity (apple-shaped) is more common among men in general. We hypothesize that the obesity may be increasing the risk of lumbar syndenomphytes as well as buckling in males due to the mechanical forces, which may not be seen in generally ‘pear-shaped’ women, where the fat tissue and mechanical forces spare the lumbar spine.

PROTEIN BIOMARKERS ASSOCIATED WITH ENTHESITIS IN PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Enthesitis, Biomarkers

1Queen’s University Belfast, Centre for Experimental Medicine Queens University Belfast, Belfast, United Kingdom; 2Atturos Ltd., University College Dublin, Dublin, Ireland; 3Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom; 4UCD Conway Institute, University College Dublin, University College Dublin, Dublin, Ireland

Background: The presence of enthesitis in PsA may provide clues to disease pathogenesis, aid diagnosis and contribute to poor prognosis. Ultrasound is an invaluable tool in assessing entheseal disease, but it requires training and is time consuming. We investigated whether enthesitis may be measured by changes in serum proteins and as such allow us to better understand, diagnose and treat this condition.

Objectives: To use mass spectrometry (MS) based proteomics to identify protein biomarkers that may be associated with those PsA patients who suffer from enthesitis.

Methods: Serum was collected as part of a prospective observational study from PsA patients who fulfilled the CASPAR criteria and were ≥ 18 yrs. All patients were biologic naive and due to commence biologic treatment. We utilised the MADrid Sonographic Enthesitis Index (MASEI) to assess US confirmed enthesitis with a score of ≥ 18 suggesting significant enthesitis and <18 determined to be non-significant. The samples were analysed using targeted MS multiple reaction monitoring (MRM) analysis with > 200 candidate proteins. The MRM data was analysed in 3 ways: 1) Raw with no normalisation 2) Normalisation to 7 stable isotopically labelled peptide spike-ins (SIL7) correcting for fluctuations in sample injections/mass spectrometry loading; and, 3) Normalisation to a set of endogenous peptides that represent total serum protein abundance (TSPA) correcting for different amounts of total serum across samples. Univariate analyses and multivariate machine learning Random Forest (RF) modelling were performed.

Results: 80 samples were analysed. 29 patients had a MASEI score of < 18 [36.25%] and 51 had a score > 18 [63.75%]. We identified 35 candidate proteins from all data sets that are included in Figure 1. RF multivariate analysis of all data revealed a set of peptide signatures with the ability to differentiate between MASEI scores < 18 vs ≥ 18. RF models generated from the peptide data had a testing and training AUC of 0.789 [95% CI 0.65, 0.93] 0.953 [95% CI 0.92, 0.98] (Raw), 0.83 [CI 0.74, 0.94], 0.972 [95% CI 0.96, 0.99] (TSPA7) and 0.845 [95% CI 0.72, 0.97]0.966 [95% CI 0.94, 0.99] (SIL7) respectively.

Conclusion: We have identified serum proteins, within this small cohort, which are associated with enthesitis in PsA. Verification of these findings in a larger, independent dataset is the next required step. Proteins related to peptide sequences for univariate + multivariate analysis. Blue (all data sets) Green (all univariate data sets) Pink (2 Multivariate data sets) ANT3: Adenine nucleotide translocase 3 AGT:Angiotensinogen A2HSGP: Alpha 2 HS glycoprotein ALAI: Apolipoprotein A-I ARP3: Angiopoietin related protein 3 AT3: Antithrombin III CNCC: Carboxypeptidase N catalytic chain CBG:Corticosteroid binding globulin GP3: Glutathione peroxidase 3 HSPB: Heat Shock Protein HSP 90-beta HRG: Histidine rich glycoprotein IGFBP Insulin-like growth factor-binding protein complex acid labile subunit PEDF: Pigment epithelium derived factor POS: Sex hormone binding globulin PGSPD: Phosphatidylinositol-glycan-specific phospholipase D TX: Tenascin-X VDBP Vitamin D binding protein.
Background: Psoriatic Arthritis (PsA) is associated with enthesitis and synovitis which lead to bone erosions, cartilage loss, and new bone formation. High-resolution peripheral quantitative computed tomography (HR-pQCT) enables the quantitative 3D assessment of joint space width (JSW) with superior resolution compared to radiography. Whether disease-specific parameters are associated with JSW on HR-pQCT in PsA remains uncertain.

Objectives: To assess HR-pQCT joint space outcomes by comparison with radiographs and investigate the relationship between disease-related variables and JSW on HR-pQCT in PsA patients.

Methods: PsA patients who underwent HR-pQCT examination (XtremeCT I, SCANCO Medical AG, Brüttisellen, Switzerland) of the second to fourth metacarpophalangeal joint were recruited in this cross-sectional study. The joint space domain on standard radiography was scored using the Sharp/van der Heijde joint space score. SvdH score was used to estimate the ability of HR-pQCT to predict SvdH scores. Linear regression models were used to determine the association between disease-related variables and JSW. JSW parameters MCPJ 2, 3 and 4 were excluded due to poor image quality.

Results: 67 patients (47 (55.2%) males; median age: 57.0 (53.0, 63.0); median disease duration: 21 (16, 28) years) were included in this analysis. Most had mild disease activity [Disease Activity index for PsA (DAPSA); 10.1 ± 6.6]; 56/67 (84%) were on conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) while 27/67 (40%) were on biologic DMARDs (bDMARDs). 11 MCPJ 2, 9 MCPJ 3 and 7 MCPJ 4 were excluded due to poor image quality. Individual MCP joint space parameters were presented in Table 1. Subluxations were detected more frequently by HR-pQCT than radiographs. SvdH score was positively associated with mean JSW (MCPJ 2-4); while use of bDMARDs was negatively associated with mean JSW (MCPJ 2) (Figure 1). Use of csDMARDs was negatively associated with Min JSW (MCPJ 3); while use of bDMARDs was positively associated with Min JSW (MCPJ 2). Longer disease duration (MCPJ 2-3) and higher ESR level (MCPJ 3) were negatively associated with mean and Min JSW (MCPJ 2) (Figure 1). Use of csDMARDs was negatively associated with mean JSW (MCPJ 3); while use of bDMARDs was positively associated with Min JSW (MCPJ 2). Conclusion: HR-pQCT could be widely used for assessing joint damage prior to evidence of radiographic joint damage in PsA patients. Higher inflammatory burden as reflected by longer disease duration, higher ESR levels, and damage joint count was negatively associated with mean, Max, and Min JSW, while suppression of inflammation using bDMARDs seems to prevent a decline in JSW.

Background: Psoriatic arthritis (PsA) is a chronic inflammatory systemic disease associated with several comorbidities. Few data are available concerning the association between psoriasis (PsO) and lung disease (LD), such as chronic obstructive pulmonary disease (COPD) and interstitial lung disease (IILD). This association has also been hypothesized in PsA. Therefore, evaluating distinct lung manifestations in PsA could be an important driver to improve patients’ management.

Objectives: To assess the prevalence and clinical features of PsA, to examine the co-occurrence of different LDs patterns and to evaluate their impact on clinical outcomes.

Methods: We performed a cross-sectional observational study including patients with diagnosis of moderate to severe PsA and at least one chest imaging (as CT scan) performed at the beginning of bDMARD therapy, referred to our Rheumatologic Unit. Demographic, clinical data and concomitant comorbidities were collected. We used Chi-square test for categorical variables and Student’s T test for continuous variables.

Results: 288 PsA patients were evaluated. Patients’ characteristics are shown in Table 1. We observed 28 patients affected by COPD (9.7%) and 7 by IILD (2.4%). About 20% of patients had radiological abnormalities without a distinct clinical diagnosis. In particular, 23 patients presented aspecific nodules (9.4%), 19 signs of bronchitis or emphysema (6.6%) and 17 interstitial thickening (5.9%). Notably, smoke (HR 2.2, p 0.04), higher age at PsA diagnosis (53.8 ± 8.5, p<0.001), higher BMI (28.6 ± 5.6, p 0.05) and recurrent infections (HR 12.3, p<0.001) were associated to COPD. Among comorbidities, cardiovascular diseases (HR 3.8, p<0.005), dyslipidaemia (HR 3.6, p<0.007) and diabetes (HR 4.1, p<0.001) were associated to COPD. Both COPD patients (HR 3.3, p<0.01) and patients with other LDs (HR 2.9, p<0.002) had a history of bDMARDs failure of at least >3 bDMARDs underwent, significantly more than patients without LD. Even in IILD patients, we observed an older age at PsA diagnosis (58 ± 12.5, p<0.01) and a higher prevalence of diabetes (HR 4.1, p<0.01) compared to patients without LD. Furthermore, nail psoriasis (HR 4.7, p<0.05) and malignancy (HR 7.1, p<0.01) were related to IILD.

Conclusion: Our results confirm the prevalence of COPD in PsA patients and add evidence about the co-occurrence of other LDs in PsA. Risk factors associated with the presence of LD emerged from our analysis, highlighting an occult untreated need in PsA patients. Moreover, we observed as LDs in PsA patients could influence bDMARDs failure. Otherwise, focusing on pulmonary comorbidities could improve therapeutic response and clinical outcomes.

POS0872

**SYNOVIAL TISSUE FEATURES ASSOCIATED WITH POOR PROGNOSIS IN INFLAMMATORY ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Synovium, Psoriatic arthritis

1Hospital Clinic, Rheumatology, Barcelona, Spain; 2Hospital General Granollers, Rheumatology, Granollers, Spain

Background: Rheumatoid arthritis (RA), Psoriatic arthritis (PsA), and undifferentiated arthritis (UA) are chronic immune-mediated inflammatory diseases characterized by joint inflammation. However, the prognosis related to progression to chronic and erosive disease or to an autoimmunized outcome could be different between those clinical phenotypes. Synovial lymphoid neogenesis (LN) has been previously studied as a prognostic factor in RA but results were conflicting between studies [1,2].

Objectives: To evaluate the potential association of inflammatory cell infiltrates and the expression of ectopic LN structures in synovial tissue (ST) with poor prognosis factors (PPF) in patients with RA, PsA, and UA.

Methods: This is a retrospective study including patients with active RA, PsA, and UA who had ST obtained by rheumatological arthroscopy in our department. We evaluated clinical data and synovial LN and the cellular infiltrate by immunohistochemistry, as previously detailed [1]. Patients who were on Biologic Disease-modifying Antirheumatic Drug (bDMARD) at the time of arthroscopy were excluded. PPF in patients with RA and UA were defined by anti-cyclic citrullinated peptide/protein antibodies (ACPA) and/or rheumatoid factor (RF), development of erosive disease or the initiation of bDMARDs during the follow-up. PPF in patients with PsA were correlated by high levels of acute phase reactants (ESR and/or CRP), dactylitis or nail involvement at the time of arthroscopy and/or the initiation of bDMARDs. Statistical analysis was done with SPSS Statistics 27 program. For the analysis of LN and PPF, we performed x²-Test to compare PPF with the cellular density and Spearman’s rank correlation coefficient for cellular density and disease activity score 28 (DAS28).

Results: A total of 87 patients were included: 26 RA, 32 PsA, and 29 UA. Demographic characteristics are detailed in Table 1. Seventeen out of 26 (65.38%) RA patients had LN and 14 (53.84%) had PPF. Twelve patients (48%) had LN and PPF, LN was associated with PPF (p<0.038). In PsA group, we found LN in 16 out of 32 (50%) and PPF in 42.4%. Polynuclear PsA (58.5%) was the most frequent phenotype and 15.2% of patients had onychopathy. Nevertheless, LN was not associated with PPF. Patients with PPF had a higher CD15+ polymorphonuclear cell density (477.63 [SD 410.68] vs 99.63 [SD 93.23] cells/cm2 in patients without PPF, p<0.031). Thirteen out of 29 (44.82%) UA patients had LN and 55.17% had PPF. The final diagnosis for these patients was: 12 RA, 4 PsA; 8 peripheral SpA and 5 remained as UA. LN was not associated with PPF. Synovial CD68+ macrophages density (lining, sublining and total) was negatively correlated with DAS28 CRP (r=-0.27, p=0.024).

Conclusion: Synovial LN was associated with PPF only in patients with RA, suggesting the specific pathogenic role that these well-compartmentalized lymphoid aggregated play in RA. However, in PsA, PPF was associated with synovial CD15+ neutrophils density, probably related to the pathogenic relevance of myeloid cells in this disease. Finally, synovial CD68+ macrophages negatively correlated with disease activity in UA patients, probably reflecting the heterogeneity of pathogenic mechanisms occurring in this group. Although this study is retrospective and with relatively small cohorts, the findings suggest a great heterogeneity of the ST features and its pathogenic implications in the subtypes of inflammatory arthritis studied.

**REFERENCES:**

Background: Patients with rheumatoid arthritis (RA) may experience feelings of guilt and shame related to the impact of the disease on their quality of life. However, patients with psoriatic arthritis (PsA) face an aesthetic problem in addition to the functional disability.

Objectives: The purpose of this study was to determine whether patients with PsA experience more feelings of shame and guilt than patients with RA.

Methods: We conducted a cross sectional study including patients with RA (ACR/EULAR criteria) and PsA (CASPAR criteria). Feelings of guilt and shame were assessed using the Experience of Shame Scale (ESS) [1] and the Test of Self Conscious Affect- Version 3 (TOSCA-3S) [2].

Results: A total of 40 RA patients (36 women, 4 men) and 30 PsA patients (12 women and 18 men) were included. The mean age was 54 years (25-75) and 51 years (21-80), respectively. The mean disease duration was 12 years (3-33) in RA patients and 13 years (2-20) in PsA patients. Illiteracy was noted in 22% of RA patients and in 5% of PsA patients. Regarding the professional status, 42% of RA patients and 50% of PsA patients were employed. High disease activity was noted in 42% of RA patients and in 13% of PsA patients. The mean total score of ESS was 45 [27-80] in RA and 65 [31-98] in PsA. There was a significant difference between the groups (p<0.001). The mean subscale scores were significantly higher among PsA patients: the characterological shame (29 vs 19, p=0.05), the behavioral shame (25 vs 18, p=0.001), and the bodily shame (10 vs 7, p<0.001). For the TOSCA-3S, the mean "shame self-talk Total" score was higher in PsA patients, but the difference was not significant (35 vs 33, p=0.453). The mean "guilt self-talk Total" score was 48 in RA and 47 in PsA (p=0.341).

Conclusion: Feelings of guilt and shame are experienced by both PsA and RA patients. However, PsA may have a higher psychosocial impact. Therefore, effective management of the dermatological and psychological aspects is necessary.

ASYMPTOMATIC HELL ENTHESITIS IN PSORIASIS PATIENTS: AN ULTRASOUND STUDY

Keywords: Enthesitis, Ultrasound, Psoriatic arthritis

R. Ben Aissa1, S. Boussaid1, S. Rekik2, S. Rahmouni1, S. Jemmali1, K. Zouaoui1, H. Srairi Sahli1, M. Elleuch1. 1Rabta Hospital, Department of Rheumatology, Tunis, Tunisia

Background: Enthesitis is a common clinical feature of psoriatic arthritis (PsA) especially in lower limb. Clinical screening for enthesitis in patients with psoriasis before developing PsA may be non-specific. Ultrasound has shown its value in the study of entheses.

Objectives: To assess heel entheses of asymptomatic psoriatic arthritis patients and healthy control using ultrasound.

Methods: We conducted a cross-sectional case-control study including psoriatic arthritis patients with no rheumatic symptoms and symptoms and age-matched healthy controls. We assessed the affected skin surface (SC) and the psoriasis severity score (PASI). Ultrasound evaluation of the calcaneal enthesis (CE) and the plantar fascia enthesis (PFE) was performed. Ultrasound abnormalities sought were: hypochoicogenicy, enthesis thickening, bursitis, cortical erosion, calcification, enthesophyse, and presence of Doppler signal.

Results: A total of 76 patients (38 cases and 38 controls) were recruited with a mean age of 51.9±15 [19-76] years and male predominance (60%). On clinical examination, pressing pain was present at the CE and PFE in, respectively, 17% and 22% of patients and with no significant difference comparing to controls (10%; EC; 10% PFE respectively) (p=0.777; p=0.259 respectively).

On ultrasound, 60% of psoriasis patients had at least one ultrasound abnormality at the CE versus 17.5% of controls (p<0.001). The most observed ultrasound abnormalities at the CE were: entheseophyte (n=17), enthesis thickening (n=15), erosions (n=11) and hypochoicogenicy (n=5). The PFE was less affected on ultrasound, presenting abnormalities in 42.5% of psoriasis patients versus 12.5% of controls (p=0.410). Erosions (n=13) and enthesis thickening (n=12) were the most observed abnormalities. The presence of ultrasound abnormalities at the PFE in psoriasis patients was correlated with age (p=0.012) and disease duration (p=0.015). Psoriasis severity according to SC and PASI was not associated with the presence of ultrasound abnormalities at the CE versus 17.5% of controls (p<0.001) and 12.5% of controls but with no significant difference comparing to controls (10%; EC; 10% PFE respectively) (p=0.777; p=0.259 respectively).

Conclusion: Our study showed that psoriasis patients could have asymptomatic heel entheses with greater involvement of the CE. Psoriatic arthritis patients need regular monitoring and screening for early symptoms of PsA.

A COMPARISON OF PSA AND RA PATIENT PROFILES REQUIRING ADVANCED THERAPIES: PSA PATIENTS ACCESS TO THE ADVANCED THERAPIES EARLIER THAN RA

Keywords: bDMARD, Psoriatic arthritis, Rheumatoid arthritis

S. B. Alikguz1, U. Gazel1, R. Chowdhury1, C. Ivory1, A. Zahraei1, E. Hepworth1, S. Aydin1. 1University of Ottawa, Rheumatology, Ottawa, Canada; 2The Ottawa Hospital Research Institute, Rheumatology, Ottawa, Canada

Background: International guidelines recommend switching to advanced therapy (AT) in patients with Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), when conventional synthetic disease modifying antirheumatic drugs (csDMARD) fail. There are several factors playing a role in that decision, including patients’ comorbidities and choices as well as the availability of the treatments.

Objectives: Here we present the results of a comparison of PsA and RA patient profiles requiring advanced therapies, from our pilot biologics clinic. Better patient outcomes in one disease may help us to recognize what can be improved in the other.

Methods: Biologics clinic is a new initiative at Ottawa Hospital aiming to improve the long-term outcomes. Patients who are about to start or switch advance therapy are evaluated at the biologics clinic. Extensive data regarding disease history, medication exposure and disease activity are collected in a standardized fashion; the comorbidity burden is documented. A protocolled ultrasound (US) is conducted at baseline and three-month intervals, until reaching remission. The data presented here represent a pilot exploratory comparative analysis.

Results: PsA (n=18) and RA (n=42) patients had similar demographic features, other than RA patients being older (table 1). The majority of the comorbidities were similar in both groups, although PsA patients had more frequent liver disease numerically (5 (27.8 %) vs 5 (11.9%), p= 0.149) and less alcohol use (19 (38.9%) vs 7 (45.2%), p= 0.649). PsA patients had more frequent moderate/severe depression using the PHQ (61.1% of PsA vs 26.2% of RA; p=0.01). For disease activity, PsA patients tend to have higher disease activity based on the TJC, HAQ and physician global; in addition to significantly longer morning stiffness than RA (Table 1). Conversely, the disease activity within the joints based on the US scores of RA patients were higher. Disease duration at the time of initiation of the first advanced therapy was significantly shorter in PsA patients (median (IQR) 10 (7.75) years) compared to RA (6 (12.5), p=0.005) and PsA patients were treated with less numbers of csDMARD.

Conclusion: According to our preliminary data, PsA patients access to advanced therapy earlier than the RA. This may be due to the heterogeneity of PsA, such as manifestations other than the joint inflammation (enthesitis and axial disease) determining treatment decisions. PsA patients also had more frequent liver disease, which also may have prevented initiation of csDMARD and led to expedited initiation of the advance therapy- as early as at diagnosis. Whether earlier access leads to better patient outcomes in PsA, will be investigated with long-term follow up. PsA patients having more tender joints despite less severe US scores may be due to the proximity of the enthesis to the joints and difficulties to differentiate entheseal pain from joint involvement by the physical exam. The use of US may improve the assessment of the domains in PsA leading to choosing the right treatments.

SCREENING FOR THE EARLY IDENTIFICATION OF PSORIATIC ARTHRITIS WITH AXIAL INVOLVEMENT (APSA) IN A COHORT OF ITALIAN PATIENTS AFFECTED BY PSORIASIS: RESULTS OF A DERMORHEUMATOLOGIC CROSS-SECTIONAL STUDY (ATTRACT)

Keywords: Diagnostic tests, Psoriatic arthritis, Spondyloarthritis

P. Vatalà1, M. Luchetti2, I. Cirimalli3, A. Agostinelli1, C. Macchiini1, R. Scordilò1, M. Gigli1, L. Massaccesi2, F. Florini1, V. Marconi1, L. Perini1, M. Ciferri2, M. Carotti2, A. Giovagnoni2, G. Polonara2, F. Sessa2, A. Campanati1, M. Giannoni3, F. Diotalevi1, A. Maraini4, A. Offidani4.
Background: Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease characterized by different domains.[1] Interest is growing towards early diagnosis of axial PsA (AxPsA), to allow better disease characterization and well-timed targeted therapeutic strategies.

Objectives: In this study, we report preliminary results of a rheumatological screening strategy settled in a dermatological centre. Primary objective is to validate the screening tool in a cohort of Italian patients affected by psoriasis, improving early diagnosis of AxPsA. Secondary objectives are: 1. classification and characterization of axial involvement; 2. profiling of patients’ characteristics and comorbidities.

Methods: Patients were enrolled in the ATTRACT study (Axial psoriasiAic arThritis scReening AnCona (Italy) according to the following inclusion criteria: age > 18 years; 2. diagnosis of psoriasis (PsO) by a dermatologist; 3. capacity to understand and sign the informed consent. Patients who assumed any DMARD 12 weeks prior to screening were excluded. Study design is shown in Figure 1. The Dermatologic-Centred Screening (DCS) tool, recently validated for early identification of AxPsA, was translated in Italian and administered to outpatients in the dermatological clinic. Patients were divided in the following groups based on answers to the Inflammatory Back Pain (IBP) related questions of the DCS: A, no affirmative answers (low AxPsA probability); B, all affirmative answers (high probability); C, only two affirmative answers (intermediate probability). Group B & C patients underwent complete rheumatological examination comprehensive of clinimetric, laboratoristic and genetic data; Xray and MRI imaging of the whole spine and pelvis were performed in all of them classifying in: a. confirmed AxPsA, b. peripheral PsA involvement only; c. PsO excluded.

Results: N.366 patients were screened; n.101 met exclusion criteria. N.91 (34.3%) were classified as group A, n.125 (47.2%) as group B, n.49 (18.5%) as group C. Following characteristics were notable: a. female sex more represented in group B; b. mean age higher in group C; c. onychopathies more represented in group A & C. List of patients’ clinical characteristics is shown in Table 1 Among group B patients, n.29 (22.4%) - B1: were classified as PsO excluded; n.22 (17.6% - B2) as isolated per-PsA (according to CASPAR criteria), n.39 (31.2% - B3) as AxPsA (n.34 fulfilling ASAS criteria, n.31 with concomitant per-PsA). Among group C, n.15 (30.6% - C1) as PsO excluded; n.3 (6.1% - C2) as isolated per-PsA, n.5 (10.2% - C3) as AxPsA (n.4 fulfilling ASAS, n.5 with concomitant per-PsA). N.13 patients are still awaiting results of imaging; n.49 (n.24 group B, n.25 group C) refused to undergo imaging and were considered lost at follow-up.

Conclusion: The DCS tool may be useful for PsA screening in a real-life cohort of PsO patients, an Inflammatory Back Pain was reported by about half of the screened PsO patients. This tool helped to identify a substantial number of naïve patients not only affected by AxPsA but also by peripheral PsA in a purely dermatological setting.

Figure 1. Design of the study
Methods: TReasure is a national, multicentre, longitudinal, and observational database, initiated in Turkey in 2017 and now includes 17 centres [1]. PsA patients with/without more than 6 months from the onset of symptoms to diagnosis were evaluated. Demographic characteristics of the patients (age, gender, delay in diagnosis), smoking (ever), BMI, andCCI score were calculated. PsA and associated disease characteristics; dactylitis, enthesitis, uveitis, IBD, saccroiliitis by mNY, disease activity at bDMARD initiation; SJC (66 joints), TJC (68 joints), ASDAS-CRP, ASDAS-ESR, BASDAI, ESR, CRP, VAS (physician global, patient global), function and quality of life; BASFI (>40 mm), HAQ-DI (<0.5, 0.5-1.0, >1.0). EQ5D, were assessed and compared between the two groups.

Results: In TReasure database, the time between symptom to diagnosis was known in 865/911 (94.9%) of PsA patients. More than 6 months of delay in diagnosis was present in 627/965 (72.4%) patients. In delayed-diagnosis group time from symptom onset to initiation of bDMARD was longer (6.1 (3.3-6.1) vs 2.4 (0.8-7.1) years, p<0.001). Patients with delay in diagnosis of PsA had more sacroiliitis (57.3% vs 46.2%, p=0.014) according to mNY criteria. However, dactylitis was more common in patients with less than 6 months of delay in diagnosis (31.2% vs 19.1%, p<0.001).Patients’ ASDAS-CRP and VAS-Physician Global score were slightly higher, while other activity parameters were similar; (ASDAS-ESR, BASDAI, BASMI, VAS patient global, SJC and TJC) (Table 1). There was no difference between the median (IQR) BASFI and HAQ-DI scores in delayed-diagnosis group, whereas BASFI and HAQ-DI categories showed worse function and quality of life. EQ5D showed similar result with slightly worse scores in delayed-diagnosis group.

Conclusion: Approximately three-quarters of PsA patients using bDMARDs have a delay of at least 6 months in diagnosis. Delay in diagnosis significantly prolongs the time until bDMARD initiation. The most important clinical finding in earlier diagnosis group is dactylitis. Axial involvement may be a reason, perhaps the result, of the delay in diagnosis. Since the delay in diagnosis is related to poor function and quality of life, efforts should be made for early diagnosis at every stage.

**COMPARATIVE DISEASE BURDEN IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSAIRITIS OR ANKYLYING SPONDYLITIS: DATA FROM COVAD PATIENT-REPORTED E-SURVEY**

Keywords: Psoriatic arthritis, Rheumatoid arthritis, Spondyloarthritis.
(Table 1, Figure 1). Patients with inactive AS had higher mean global physical health scores than RA patients (13.13 ±2.93 VS RA 12.48 ±2.90, p=0.01, Table 1). Those with inactive RA or PsA showed more severe fatigue (PsA 10.58 ±2.22, RA 10.45 ±4.08 VS 9.4 ±4.13, p <0.01 for both). Patients with inactive RA also reported poorer physical function and more residual pain than those with AS (37.79 ±8.86 VS 41.13 ±7.79, p<0.001; 3.87 ±2.45 VS 3.34 ±2.39, p=0.01, respectively). Similarly, residual pain was perceived as higher in patients with inactive PsA than those with AS (4.04 ±2.50 VS 3.34 ±2.39, p=0.01)

Conclusions: Disease burden is roughly comparable in patients with active RA, PsA or AS. Patients with inactive RA and PsA suffer higher disease burden than those with inactive AS.

Behrens2,3, 1Frankfurt University Hospital, Rheumatology, Frankfurt am Main, Germany; 2Fraunhofer ITMP - Translational Medicine and Pharmacology, Clinical Research, Frankfurt, Germany; 3Fraunhofer Cluster of Excellence Immune Mediated Diseases OIMD, Clinical Research, Frankfurt, Germany; 4Fraunhofer-Institut für Intelligente Analyse- und Informationssysteme IAIS, Healthcare Analytics, Sankt Augustin, Germany

Background: Psoriasis (PsO) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to PsO. Up to 30% of the PsO patients will develop PsA during skin disease course. Defined and validated approaches for early detection are still missing. Beside biomarkers from blood or imaging, clinical characteristics of the patients may be of value to detect PsA patients in the transition state early.

Objectives: To perform an AI-based cluster analysis in a cohort of PsO patients at-risk for development of PsA to assess clinical characteristics as markers for early PsA.

Methods: Clinical data sets from the recently published XCITING study [1] were used to perform an AI based analysis using the attributes "tenderness of joints
Results:
Characteristics of the XCITING cohort were described previously [1]. After performance of the cluster analysis, seven different cluster types were identified (cluster 0-6) according to the clinical data sets of the cohort by use of the attributes and tested for their significance to predict the presence or absence of MSK inflammation in PsO (swollen joints, positive MSUS or positive FOI). Three "tenderness clusters" out of 7 were identified with significant correlation: while as expected cluster 2 (no major findings in LEI and TJC) is associated with no inflammation, "feet-type" involvement (cluster 4) and dominance atPIP and DIP joints (cluster 6) (Figure 1, Table 1) are associated with MSK inflammation at the hands.

Conclusion: Markers for early detection of PsA patients who will develop PsA are missing. Within this analysis we show, that by use of clinical data sets only, risk profiles developed from finding of tenderness at different anatomical regions might be helpful for detection of inflammatory MSK processes. Interestingly, the feet tenderness can also predict MSK inflammation at the hands. A combination of both, clinical data sets and liquid/imaging biomarkers may be identified on base of this observation to increase the potential to detect PsO patients with high-risk profiles for PsA early.

POS0883 SCREENING/REFERRAL STRATEGIES FOR THE EARLY RECOGNITION OF PSA AMONG PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS OF A GRAPPA SURVEY

Keywords: Psoriatic arthritis, Diagnostic tests

K. Song1, L. Webb1, L. Eder2, O. Fitzgerald3, N. Goe4, P. Hellwell5, A. Katz6, J. F. Merola7, C. Rosen8, L. Coates9, D. Podububny10, 1University of Oxford, Medical Sciences Division, Oxford, United Kingdom; 2University of Toronto, Department of Medicine, Toronto, Canada; 3University College Dublin, School of Medicine, Conway Institute for Biomolecular Research, Dublin, Ireland; 4Duke University School of Medicine, Department of Medicine, Division of Rheumatology, Durham, United States of America; 5University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 6... 7Brigham and Women's Hospital, Department of Dermatology, Boston, United States of America; 8Toronto Western Hospital, University of Toronto, Division of Dermatology, Department of Medicine, Toronto, Canada; 9University of Oxford, Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom; 10Charite University, Department of Rheumatology, Berlin, Germany

Background: Diagnostic delay in psoriatic arthritis (PsA) is associated with poorer outcomes, and early screening/ referral strategies are important to reduce the delay. Implementation of early screening approaches demands cooperation between rheumatologists, dermatologists and primary care providers (PCPs).

Objectives: To explore the experiences of dermatologists and rheumatologists in the early recognition of PsA and suggest improvements to the current shared-care model.

Methods: A 24-question survey addressing referral strategies was constructed within GRAPPA (Group for Research and Assessment of Psoriasis and Psoriatic Arthritis) and sent to all members (n=927). Questions addressed the use of screening tools, interspecialty involvement in therapeutic decision making, and suggestions for earlier recognition.

Results: Surveys were completed by 113 rheumatologists from 37 countries (across six continents) and 26 dermatologists from 16 countries (across 4 continents), with a mean of 21.7 ± 10.7 and 18 ± 12.3 years experience, respectively. Of dermatologists, 81% use PsA-specific screening instruments. Conversely, rheumatologists reported that only 27% of patients referred to them from all sources had been assessed with screening tools. Across both specialties, "PST" was reported to be the most used tool. Whilst dermatologists reported that 67% ± 28% of their suspected PsA cases were confirmed, rheumatologists felt −48% ± 24% of suspected PsA cases were confirmed. Both specialties (n=137) reported similar views regarding optimisation of the diagnostic process: 78% believed that the best approach involved combining patient-reported and physician-confirmed findings (see Figure 1A). Moreover, the education of PCPs was seen as the greatest priority to improve screening with 76% raising this as an unmet need (Figure 1B).

Conclusion: The survey indicated the current unmet needs in the early recognition of PsA. Accordingly, important areas to address include improving the use of validated screening instruments, increasing the education of community-based dermatologists and PCPs, and utilising a combination of patient-reported and physician-confirmed findings to identify patients with a high probability of PsA among those with psoriasis.

predictors of patient-reported treatment success in PsA. We hypothesized that disease activity measures, including arthritis, psoriasis, enthesitis, and dactylitis, symptoms, and treatment type would contribute to patient-reported treatment success. We did not include multiple patient-reported outcomes in a model due to collinearity.

**Results:** A total of 178 participants had a baseline visit. Mean (SD) CASPAR score was 3.7 (0.9) age 51.7 (13.5) years, BMI 31.3 (7.2), while 52.2% were women, and 86.0% Caucasian. Treatment success was reported by 116 patients (65%). Overall, 105 participants had complete data for all the variables included in the logistic regression models. The total joint swelling 66, total joint tenderness 68, PROMIS pain interference, and PROMIS fatigue were significantly negatively associated with treatment success while controlling for age, race, gender, and BMI. Each additional swollen joint was associated with a 23% decreased odds of treatment success, each tender joint was associated with 17% decreased odds of success, each additional point on the PROMIS fatigue and on the PROMIS pain interference was associated with 6% and 15% decreased odds of success, respectively (Table 1). Patients receiving a tumor necrosis factor inhibitor (TNFi) had approximately 11-13 times increased odds of reporting treatment success compared to patients on a classical synthetic DMARD alone, while controlling for age, race, gender, and BMI.

**Conclusion:** Patient-reported treatment success was independently associated with control of tender and swollen joints, pain, fatigue, and with receiving a TNF-inhibitor medication. This supports the use of biological treatments as standard of care in PsA.

Diagnostics and imaging procedures

**POS0885** CARDIOVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS - THE ADDED VALUE OF CARDIAC MAGNETIC RESONANCE

**Keywords:** Systemic sclerosis, Imaging, Heart

Z. Gogoliska¹, Z. Smoleńska¹, A. Wojtczak⁰, A. Viteži¹, D. Kulawiak-Galaks⁰, Z. Zdrojewski¹, K. Domiak¹.¹ Medical University of Gdańsk, Department of Rheumatology, Geniatetics and Internal Medicine, Gdańsk, Poland; ²University of Naples Federico II, Naples, Italy; ³Medical University of Gdańsk, Department of Radiology, Gdańsk, Poland; ⁴Medical University of Gdańsk, Department of Noninvasive Cardiac Diagnostis, Gdańsk, Poland

**Background:** Cardiac complications of systemic sclerosis (SSc) are frequently subclinical or insidious and may affect up to 80% of patients [1], remaining one of the leading causes of death in, usually in the mechanism of life-threatening arrhythmia, heart failure or sudden cardiac arrest [2]. Diagnostic tools that can be used for heart involvement in SSc include ECG, echocardiography, serum markers (troponin, CK-MB, BNP, NT-proBNP) and, recently, magnetic resonance imaging. Cardiac magnetic resonance (CMR) with advanced tissue characterization techniques (including parametric mapping of T1 and T2 relaxation times as well as extracellular volume [ECV] fraction of the myocardium) can provide unique non-invasive insight into early (inflammation, oedema) and late (fibrosis, necrosis) stages of heart involvement in those patients [3].

**Objectives:** To assess cardiac involvement in unselected systemic sclerosis patients in both diffuse (DSSc) and localized (LSSc) clinical subgroups, using contemporary cardiac magnetic resonance imaging techniques.

**Methods:** In this prospective single-centre study, we included 20 consecutive systemic sclerosis patients (51±14 years, 14 [70%] female) in whom CMR was performed between 2013 and 2022. Their baseline CMR results, clinical presentation of SSc, medical history, laboratory tests, lung function tests, and follow-up were analyzed with special attention to CMR features of heart involvement in the course of SSc in both clinical subgroups. Moreover, CMR findings were compared to a group of healthy controls (N=37).

**Results:** Systemic sclerosis patients had significantly lower LVEF (56.6% vs 61.6%, p<0.002), higher LVEFSI (38.9/m² vs 31.6/m², p=0.002), longer T1 and T2 relaxation times (1029.3 ms vs 993 ms and 48 ms vs 44 ms, respectively; p<0.001), and higher ECV (27.9% vs 26.0%, p<0.05) as compared to healthy controls. Overall, 13 (65%) patients had at least one abnormal finding in CMR, of which in 7 (35%) baseline ECG and echocardiogram were normal or borderline normal. Additionally, heart involvement was more frequent among DSSc patients (11/13), with more severe manifestations including greater extent of dysfunction and more pronounced tissue alterations than in LSSc patients (2/7). Of note, CMR allowed for detection of subtle tissue abnormalities in 3 (15%) of patients with normal ECG and echocardiograms as well as additional new tissue information (edematous abnormal T1/T2/ECV and/or non-ischemic fibrosis) in 4 (20%) others, in whom borderline unspecific echo abnormalities were detected. During a median follow up of 3.4 (1.9,5.5) years, three patients (15%) died (heart failure - 1, gastrointestinal complications - 1 and breast cancer - 1). Treatment escalation and deescalation were required in 8 and 5 patients, respectively. Two patients had their treatment changed over the follow up period, in 5 the treatment remained unchanged.

**Conclusions:** SSc patients frequently present heart involvement, especially in DSSc type. This complication is often late diagnosed or misdiagnosed by conventional methods. Cardiac magnetic resonance with modern tissue characterization techniques, provides detailed insight in heart involvement in systemic sclerosis. Modern quantitative techniques allow for early diagnosis, thus prompt closer follow up and/or treatment decisions in a proportion of patients in whom other diagnostic tests were inconclusive.

**POS0886** 18F-FDG PET-CT OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH EARLY SYSTEMIC SCLEROSIS

**Keywords:** Systemic sclerosis, Lungs, Imaging

B. Broers¹, G. C. J. Zweerijnen⁰, E. Nossent⁰, L. Meijboom⁰, M. Yaqub⁰, J. Spijker³, J. De Vries-Bouwstra,⁴ J. M. Van Laar⁰, C. J. Van der Laken⁰, A. Voiskuyl⁰.¹ Amsterdam UMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; ²Amsterdam UMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands; ³Amsterdam UMC, Pulmonary Medicine, Amsterdam, Netherlands; ⁴Amsterdam Cardiovascular Sciences Research Institute, Amsterdam UMC, Amsterdam, Netherlands; ⁵UMC Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; ⁶UMC Leiden, Rheumatology, Leiden, Netherlands

**Background:** Patients with systemic sclerosis associated interstitial lung disease (SSC-ILD) have a highly variable disease course, which makes clinical management challenging [1]. Hence, there is a clinical need for new tools to improve patient monitoring and stratification. 18F-Fluorodeoxyglucose (FDG) PET-CT of the lungs has previously shown promising results in patients with SSC-ILD by reflecting ILD activity and contributing to the prediction of lung function decline [2]. However, as most studies have been performed in patients with longstanding and severe ILD, there is limited information concerning the value of 18F-FDG PET-CT in the first two years after SSC diagnosis and the recognition of early ILD.

**Objectives:** To prospectively investigate the presence and severity of ILD as detected by 18F-FDG PET-CT in patients with early SSc.

**Methods:** Included patients fulfilled the 2013 ACR-EULAR classification criteria for SSc, had a disease duration ≤ 2 years (from onset of first non-Raynaud’s symptoms) and diffuse cutaneous disease. All patients underwent a high-resolution CT scan of the lungs to evaluate the presence of ILD, as part of routine clinical care, as well as pulmonary function tests. 18F-FDG PET-CT was performed in 13 patients (ILD n=9; no ILD n=4). For quantitative analysis, six volumes of interest (VOIs) of 2cm were placed in pre-specified dorsobasal lung areas, as described previously [3]. The six standardized uptake values (SUV) were processed and averaged to obtain a total SUV for the dorsobasal lung fields. To correct for inter-individual differences, all uptake values were corrected for 18F-FDG uptake in the mediastinal blood pool [3]. Statistical analysis was performed using a Mann-Whitney U test to compare for between-group differences.

**Results:** In the ILD group, 7/9 (78%) of the patients were male with an average age of 53.2 years. In the non-ILD group 2/4 patients were male (50%), with an average age of 41.3 years. All patients received immunosuppressive treatment with either Mycophenolate Mofetil (ILD 100%; no ILD 50%) or Methotrexate (ILD 0%; no ILD 50%) before inclusion. Quantitative analysis of 18F-FDG PET-CT revealed that SUVmax corrected in the dorsobasal lung fields was higher in the patients with ILD (median [range] 0.90 [0.85]) than in patients without ILD (median [range] 0.63 [0.15]; p=0.03). The higher 18F-FDG uptake in patients with ILD compared to those without ILD is visually illustrated in Figure 1. The relationship between the uptake of 18F-FDG, high-resolution CT scan of the lungs and pulmonary function tests at baseline is currently under analysis (and will be presented during the meeting).

**Conclusion:** Our results suggest that in early disease stages, within two years of SSc diagnosis, 18F-FDG uptake in the dorsobasal lung fields is higher in patients with ILD compared to patients without ILD. Further analysis is warranted to investigate 18F-FDG uptake in other lung regions, its relationship to conventional tools and with regard to treatment outcomes. As such, we will investigate repeated 18F-FDG PET-CT and clinical outcomes after 1 year of follow-up in patients with SSc-ILD.

![Figure 1. Pulmonary uptake of 18F-FDG in patients with diffuse cutaneous SSC without ILD (A) and with ILD (B). 18F-FDG uptake is indicated by the yellow arrows.](image-url)
Background: Skin involvement is a hallmark of systemic sclerosis and an important marker of disease activity, severity and prognosis.[1] The modified Rodnan skin score (mRSS), the current gold standard for the evaluation of the skin in SSc, both in clinical trials and in practice, has several limitations.[2] This highlights the need for more sensitive and objective measures of skin involvement, not only support the evaluation and development of new treatments, but also to facilitate the earlier diagnosis of SSc. Normal reference curves for skin ultrasound parameters, considering relevant influential factors seem of pivotal importance to fully exploit the potential of these new techniques as reliable tools for diagnostic and follow-up purposes.

Objectives: Our primary objective was to establish preliminary normal reference curves for ultrasound dermal thickness and skin stiffness, in the 17 Rodnan skin sites, considering the effect of gender and age on these measures. As an exploratory objective, we investigated the effect of body mass index and the menopause on skin ultrasound measures.

Methods: A cross-sectional study was conducted involving 140 healthy volunteers, aged 20-79 years. Recruitment was stratified for age (10-year categories) and gender to guarantee a balanced distribution of these factors in the sample. Participants were excluded if they had any of the following conditions: (1) diagnosis of any skin or connective tissue or rheumatic illness, (2) history of insulin treated diabetes, (3) history of anticoagulant or radiotherapy treat- ments, (4) exposure to organic solvents, (5) past glucocorticoid treatment for more than 4 months or (6) recent (<4 weeks) treatment with glucocorticoids, regardless of dose, clinical indication and timing. Ultrasound dermal thickness and skin stiffness were assessed by high-frequency ultrasound (18MHz) and shear-wave elastography (9MHz), respectively, at the 17 Rodnan skin sites. All ultrasound measures were performed in the morning (between 9:00 and 13:00 hours) in the same room and at stable temperature. Outcomes were evaluated through a mixed linear model, univariate, and multivariate regressions. Normal reference curves were derived for both ultrasound measures in each Rodnan skin site, for females and males.

and males (Example in Figure 1). An online calculator of the percentiles of skin ultrasound measures was also developed. A radar chart showing these values and the percentile for each site is automatically drawn, allowing the clinician to export the results obtained.

Results: A total of 140 caucasian participants, i.e., 80 females, mean (SD) age of 47.2 (16.0) years; and, 60 males, 49.5 (17.3) years were included. Ultrasound dermal thickness and stiffness measures were higher in males than females, in all Rodnan skin sites (except in chest for ultrasound-dermal thickness). Age had also a significant impact in both ultrasound measures, but only in some skin sites. Gender and age percentile curves were plotted for each of the measures in each skin site.

Conclusion: Gender and age are strongly associated with skin ultrasound parameters, imposing the need for gender- and age-specific reference values. Normal reference percentile curves for skin ultrasound measures are promising tools to support earlier diagnosis and refine sensitivity to time- or drug-induced changes. These reference percentile curves are provided as a basis for future cooperative work to strengthen its evidence-base, representativeness and refinement and Mouthing potentially influential factors.

POS0889 ASSESSMENT OF MYOSITIS-RELATED INTERSTITIAL LUNG DISEASE BY 68GA-DATA.SA.FAPI PET-CT

Keywords: Lungs, Myositis, Imaging
K. Kastrati1, T. Nakuz2, S. Gessl1, E. Simader1, D. Mrak1, M. Bonelli1, H. Kiener1, F. Prayer2, D. Aletaha1, M. Hacker2, W. Langsteger1, T. Traub-Weidinger2, H. Radner1, P. Mandl1, D. Plant1, J. Humphreys2, A. Macgregor3, M. Yates3, S. Verstappen3, J. Bowes1, A. Barton1,1 The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; 2The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3University of East Anglia, Norwich Epidemiology Centre, Norwich, United Kingdom

Background: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous autoimmune disorders marked by skeletal muscle inflammation and extra-muscular complications including pulmonary involvement. Interstitial lung disease (ILD) is a common manifestation affecting up to 78% in IIM patients. Methods and means for in-vivo visualization of ongoing tissue remodeling in affected organs are scarce.

Objectives: To quantify and compare fibroblast activation in the lungs between IIM-patients and control subjects using 68Ga-labelled inhibitor of Fibroblast-Activation-Protein based positron emission tomography-computed tomography (68Ga-DATA.SA.FAPI PET-CT) imaging. Methods: Patients with IIM recruited prospectively from the rheumatology outpatient clinic, and control subjects without rheumatic conditions or ILD enrolled from the cardiology outpatient clinic underwent 68Ga-FAPi PET-CT imaging. Pulmonary FAPI accumulation was assessed by measuring the maximal standardized uptake value (SUVmax) and mean SUV (SUVmean) over the whole lung (wi), respectively. Values of SUV were compared across IIM patients with and without ILD and controls using analysis of variance (ANOVA) test and displayed as mean ± standard deviation (SD).

Results: The clinical characteristics of patients with IIM (15 patients with ILD confirmed by CT and 4 non-ILD patients with primary muscular affection) and control subjects (n=17) are displayed in Table 1. Subtypes of IIM included antisynthetase syndrome (57.9%), dermatomyositis (15.8%), overlap myositis (15.8%), and immune-mediated necrotizing-myositis (10.5%). In individuals with IIM-related ILD, whole-lung 68Ga-DATA.SA.FAPi uptake was significantly increased as compared to both, the non-ILD IIM patients and the control group: SUVmax (6.63 ± [2.05] vs. 3.74 ± [0.71]) and 4.74 ± [1.24] respectively, both p<0.001 (Figure 1A) and SUVmean (1.50 ± [0.48] vs. 0.94 ± [0.22] and 1.11 ± [0.34] respectively, both p<0.05) (Figure 1B). No differences of wiSUVmax or wiSUVmean were observed between non-ILD IIM patients and the control group.

Conclusion: This study demonstrates enhanced tracer uptake in 68Ga-DATA.SA.FAPI PET-CT in patients with IIM. Thus, FAPI-PET-CT may provide a useful tool for the assessment of lung disease in IIM. Further discriminatory and diagnostic testing approaches are needed to integrate this novel imaging method into clinical decision making.

POS0890 USING POLYGENIC RISK SCORES TO AID DIAGNOSIS OF PATIENTS WITH EARLY INFLAMMATORY ARTHRITIS: RESULTS FROM THE NORFOLK ARTHRITIS REGISTER

Keywords: Epidemiology, Inflammatory arthritides, Genetcs/epigenetics
R. M. Hum1, S. Sharma1, M. Stabler1, S. Viatte1, P. Ho1, N. Nair1, C. Shi1, C. F. Yap1, M. Soomro1, D. Plant1, J. Humphreys2, A. Macgregor3, M. Yates3, S. Verstappen3, J. Bowes1, A. Barton1,1 The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; 2The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3University of East Anglia, Norwich Epidemiology Centre, Norwich, United Kingdom

Background: There is growing evidence that genetic information can offer valuable information to a clinician in a diagnostic setting, and that it is feasible that
genetic data would be of benefit to the rheumatologist outpatients setting by aiding early diagnosis. A genetic probability tool (G-PROB) has recently been developed to aid diagnosis using existing knowledge of disease-associated genetic variants but has only been tested in a limited capacity.

**Objectives:** Our aim was to assess whether G-PROB could aid diagnosis in the rheumatologist outpatient setting using data from the Norfolk Arthritis Register (NOAR), a large prospective observational cohort of patients presenting with early inflammatory arthritis where diagnosis at baseline is unclear.

**Methods:** Genotypes and follow-up clinician diagnoses were obtained from patients from NOAR. Six G-probabilities (0-100%) were created for each patient based on known disease-associated odds ratios (ORs) of published genetic risk variants, each corresponding to one disease of rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), psoriatic arthritis (PsA), spondyloarthropathy (SpA), gout or “other rheumatological diseases”: Performance of the G-probabilities was assessed in the follow-up clinician diagnosis. (C) ROC analysis of correspondence of G-probability threshold # of patients with at least one G-probability at the given threshold (%)

**Table 1. Performance of G-probabilities in suggesting likely and unlikely diagnoses at different thresholds**

**Figure 1.** (A) Distribution of G-probabilities which match and those which do not match clinician diagnosis. Ideally the correct diagnosis should have higher probabilities, and the distribution should be skewed to the right, with incorrect diagnoses having lower probabilities with a distribution skewed to the left. (B) Linear regression without intercept showing concordance of G-probabilities with clinician diagnosis, where x-axis shows G-probabilities, and y-axis shows binary outcome of concordance with clinician diagnosis (y=1) and non-concordance (y=0). A regression coefficient of 1·03, where 1·00 represents perfect calibration. G-probabilities discriminated clinician diagnosis with pooled areas under the curve (95% CI) of 0·84 (0·81 to 0·86). G-probabilities <5% corresponded to a negative predictive value (NPV) of 96% where it was possible to suggest at least one unlikely diagnosis for 99-9% of patients, two or more diseases for 94% of patients, and three or more diseases for 54% of patients. G-probabilities >50% corresponded to a positive predictive value (PPV) of 74%. In 57% of patients, the disease with the highest G-probability corresponded to clinician diagnosis.

**Conclusion:** G-PROB successfully converts complex genetic information into meaningful, and interpretable conditional probabilities which may be especially helpful at suggesting unlikely diagnoses in the rheumatologist outpatient setting.

**AN END-TO-END MACHINE LEARNING PIPELINE FOR THE AUTOMATED DETECTION OF RADIOGRAPHIC HAND OSTEARTHRITIS: A NO-CODING PLATFORM EXPERIENCE**

**Keywords:** Osteoarthritis, Artificial intelligence, Imaging

**Background:** Machine learning’s performances in the field of radiology have been constantly increasing in recent years such that nowadays many algorithms equals human performances and are FDA approved.[1,2] Non-coding platforms have recently emerged and allow healthcare professionals with no programming experience to play an active role in the development of machine learning (ML) algorithms according to existing or emerging clinical needs.

**Methods:** We constituted a retrospective cohort of 19,560 patients. Using all their images, we trained different neural networks in order to select just knee AP X-rays without prosthesis or artifacts. Our work explores two approaches: the prediction of the stage of osteoarthritis according to the KL scale and the measurement of the JSW. For the prediction of the KL score, 2,081 X-rays annotated by 3 radiologists were used to train a convolutional neural network (CNN). The measurement of the JSW required the realization of 3 different annotations: the positioning of the joint, of the two condyles (medial and lateral) and the contouring of tibia and femur. Three neural networks were optimized to reproduce these annotations before calculating the JSW for each condyle. For each individual task, we decomposed the datasets into training, validation, and test sets, used different data augmentation techniques, and researched the best possible architecture.

**Results:** The Kellgren-Lawrence score prediction obtained the following performances: an accuracy of 0.92, a sensitivity of 0.84 and an average area under the ROC curve (AuC) of 0.97. To evaluate the measurement of the JSW, we calculated the correlation between the area measured by the annotators and the area predicted by the algorithms, obtaining a Pearson correlation of 0.84.

**Conclusion:** This study highlights the relevance of the use of artificial neural networks for the assessment of osteoarthritis. Their performance opens the way to a tool assisting in the precise and standardized gradation of the severity of joint degradation.

**OSTEARTHARITIS SEVERITY USING KNEE X-RAYS AND CONVOLUTIONAL NEURAL NETWORKS**

**Keywords:** Imaging, Artificial intelligence, Osteoarthritis

**Background:** Knee osteoarthritis is a heterogeneous and complex degenerative pathology, characterized by a progressive deterioration of bone cartilage and structural modifications of the joint [1]. The precision of the diagnosis and the rating of the severity are major criteria for the therapeutic management and its follow-up. They are based on three criteria: the assessment of the pain, of the functional impairment and of the structural modifications. For this last criterion, the standard protocol in routine care remains the interpretation of X-ray images using standardized scales. The Kellgren-Lawrence (KL) score, which assesses both the joint space and the presence of osteophytes, allows a classification of the stages of osteoarthritis, but it relies on subjective manual interpretation and is time consuming for practitioners [2].

**Objectives:** In this study, we have developed artificial intelligence algorithms to automatically measure the ibia-femur joint spacing (or joint space width JSW) and determine the Kellgren-Lawrence (KL) score.

**Methods:** We constituted a retrospective cohort of 19,560 patients. Using all their images, we trained different neural networks in order to select just knee AP X-rays without prosthesis or artifacts. Our work explores two approaches: the prediction of the stage of osteoarthritis according to the KL scale and the measurement of the JSW. For the prediction of the KL score, 2,081 X-rays annotated by 3 radiologists were used to train a convolutional neural network (CNN). The measurement of the JSW required the realization of 3 different annotations: the positioning of the joint, of the two condyles (medial and lateral) and the contouring of tibia and femur. Three neural networks were optimized to reproduce these annotations before calculating the JSW for each condyle. For each individual task, we decomposed the datasets into training, validation, and test sets, used different data augmentation techniques, and researched the best possible architecture.

**Results:** The Kellgren-Lawrence score prediction obtained the following performances: an accuracy of 0.92, a sensitivity of 0.84 and an average area under the ROC curve (AuC) of 0.97. To evaluate the measurement of the JSW, we calculated the correlation between the area measured by the annotators and the area predicted by the algorithms, obtaining a Pearson correlation of 0.84.

**Conclusion:** This study highlights the relevance of the use of artificial neural networks for the assessment of osteoarthritis. Their performance opens the way to a tool assisting in the precise and standardized gradation of the severity of joint degradation.

Objectives: We aimed to evaluate the feasibility of ML algorithm generation using a no-coding platform by clinicians without ML experience. By using such a platform, we developed a model for automated grading and scoring of radiographic distal interphalangeal osteoarthritis (DIP-OA) with subsequent user experience (UX) testing of the algorithm.

Methods: 13690 hands x-rays from 2863 patients within the Swiss Cohort of Quality Management (SCQM) and an external control dataset of 346 non-SCQM patients were collected and scored for DIP-OA by the modified Kellgren and Lawrence Score (K/L). 48892 DIP joints were extracted and classified according to the K/L score. Giotto (L2F, Lausanne) was used as a no-coding platform for training of 2 convolutional neural networks, the first one for segmentation of hand joints and subsequent DIP-joint extraction, and the second one for classification of KL scores according to the presence of osteophytes and joint space narrowing on the previously extracted DIP-joints. The classification model’s performance was tested by an internal test set (SCQM database) and an external test set (non-SCQM). User experience (UX) of a web app developed from the platform as a provisory user interface (UI) was investigated in rheumatologists and radiologists. The usability of heat maps was also investigated.

Results: The sensitivity and specificity of this model for detecting DIP-OA, was 79% and 86%, respectively. The accuracy for grading the KL score was 75% with a kappa score of 0.76. A similar sensitivity (79%) and specificity (80%) for detecting DIP-OA was found in an independent external test set. The accuracy per DIP-OA class differed with 79% for no OA (defined as KL 0 and 1), 65% for KL2, 40% for KL3, and 70% for KL4. On the external test set overall accuracy was 66% and the kappa score 0.75. The platform was intuitive and easy to use, but support from data scientists was still required for upload of the data set exceeding the drag and drop process. UX testing of the web app revealed a moderate demand by rheumatologists. The usability of heat maps was also investigated.

Conclusion: No-coding platforms are an opportunity to develop end-to-end AI-prototypes for further testing. Their use by clinicians without experience in programming and machine learning is possible. Here, automated radiographic DIP-OA detection is both feasible and usable, whereas grading between individual KL scores, e.g., for clinical trials, remains challenging, partly because of the inter-observer variability inherent to the scoring method.

**Differential Diagnosis between Hand Osteoarthritis and Psoriatic Arthritis Using Indo Cyanine Green-Based Fluorescence Optical Imaging**

**Keywords:** Imaging, Osteoarthritis, Psoriatic arthritis

B Drude1, O Maugesten2, S G Werner3, J Berger4, J Kotsche5, G R Burmester1, I K Haugen2, S Ohndorf1, 1Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; 3RHO (Rheumatology, Immunology, Osteology) Düsseldorf, RHO Research Institute, Düsseldorf, Germany; 4Xiralite GmbH, Research and Development, Berlin, Germany; 5Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Epidemiologic Unit, Berlin, Germany

**Background:** Fluorescence optical imaging (FOI) provides a measure of inflammation in finger joints and wrists [1,2]. Recognizing specific joint signals and morphologic patterns in FOI may be helpful in differential diagnosis of hand osteoarthritis (OA) and psoriatic arthritis (PsA).

**Objectives:** To analyze the diagnostic value of the established FOI Activity Score (FOIAS) and predefined morphologic patterns in the differentiation between hand OA and PsA.

**Methods:** FOIAS has been validated for inter- and intra-reader reliability[3]. FOI sequences were examined by one trained reader (BD). Cases with physician-based diagnosis of hand OA (n=47) and PsA (n=54) were randomly mixed and pattern recognition might be needed to expand the diagnostic capability of FOI.

**Results:** There was moderate agreement between the physician-based diagnosis of OA and PsA and the diagnosis that was proposed based on FOI findings. OA cases presented more pronounced signal enhancement in PIP and DIP joints when compared to PsA cases. Additional morphologic criteria and pattern recognition might be needed to expand the diagnostic capability of FOI.

**Ankle Retinaculum Abnormalities As Features of Psoriatic Arthritis: An Ultrasound Study**

**Keywords:** Psoriatic arthritis, Ultrasound

M Forien1, E Ebstein1, B Leger1, L Benattar2, P Dieudé1, S Ottaviani1, 1Bichat Hospital, Rheumatology, DMU Locomotion, Paris, France

**Background:** Ankles are frequently involved in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) and can be observed in both diseases. The detection of enthesisitis may support the diagnosis for PsA and help to distinguish these 2 rheumatic diseases. At ankle level, retinacula can be analyzed with ultrasonography (US) and their insertions into bones can be considered as enthesis.

**Objectives:** The aim of the present study was to compare the US assessment of the retinacula of ankles in a population of RA and PsA patients with painful ankle.

**Methods:** This was an observational cross-sectional study. We analyzed consecutive RA or PsA patients with ankle pain. We also analyzed healthy controls (HC), without rheumatic disorders nor ankle pain. The following US features were assessed: presence of synovitis of tibiotar or talonavicular joints, presence of tencynovitits of peroneal or posterior tibial tendons. Two retinacula: the anterior peroneal retinaculum (SPR) and the flexor retinaculum (FR) were also evaluated in mode B (thickness, echogenericy and presence of malleolar periostitis) and the vascularization at their insertion into bone by using power Doppler (PD).

**Results:** We analyzed data for 80 consecutive patients (60% women; median age 56 years). Among these patients, 23 (29%) and 20 (25%) were RA, PsA and HC patients, respectively. A total of 160 ankles were assessed. The evaluation of SPR did not show difference between the two diseases. Regarding the FR, we observed that FR was thicker in PsA patients than in RA (0.96mm ± 0.39 vs. 0.64mm ± 0.15, P<0.001) and HC (0.96mm ± 0.39 vs. 0.56mm ± 0.12, P<0.001) without difference between RA patients and HC. The following US features were more frequently found in PsA than in RA ankles: hypoechogenicity (46% vs 7%, P<0.001), positivity of PD (43% vs 8%, P<0.001) and malleolar periostitis (43% vs 8%, P<0.001). By using ROC curve analysis, we determined that a cut-off of 1.1mm of FR thickness provided a sensitivity of 49% and specificity of 97% for the diagnosis of PsA. The association of a thickness ≥1mm with hypervascularization of the malleolar insertion of FR, named as “retinaculitis”, was observed in 39% and 3% of ankles in PsA and RA, respectively. The proportion of retinaculitis of SPR was not different between the two diseases.

**Conclusion:** US abnormalities of FR were more frequently observed in PsA than in RA patients and appear to be specific for PsA. Thus, US assessment of FR might be useful to distinguish RA and PsA in patients with painful ankles.

**Analysis of the Performance of an Artificial Intelligence Algorithm for the Detection of Radiographic Sacroiliitis in an Independent Cohort of AxSpA Patients Including Both NR-AXSPA and R-AXSPA**

**Keywords:** Artificial intelligence, Imaging, Spondyloarthritis

E Perch1, J L Vahidi2, J Nicolao3, R Tham4, B Hoepekens5, B Utuktepe6, K K Bressem7, D Podhubny1, 1Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany; 2Charité – Universitätsmedizin Berlin, Radiology, Berlin, Germany; 3UCB Pharma, - Anderlecht, Belgium; 4UCB Pharma, - Slough, United Kingdom; 5UCB Pharma, - Monheim, Germany; 6UCB Pharma A.S., - Istanbul, Turkey

**Background:** Conventional radiography of the sacroiliac joints is the first imaging method if axial spondyloarthritis (axSpA) is suspected. The presence of definite radiographic sacroiliitis is needed to classify as radiographic (r-axSpA) based on the modified New York Criteria (mNYc). However, the reliability of radiographic sacroiliitis assessment is low, especially if performed locally. Expert central reading for classification purposes in clinical trials is time-consuming and still has high inter-reader variability. A possible solution to detect radiographic sacroiliitis with consistent reproducibility, could be the use of an artificial intelligence analysis of radiographs. Recently an artificial neural network showed an expert-level performance for classification and diagnostic settings[1,2].

**Objectives:** The aim of this study was to analyze the performance of this previously trained artificial network in a completely new cohort of patients previously evaluated as r-axSpA or nr-axSpA by central readers.

**Acknowledgements:** NIL.

**Disclosure of Interests:** None.

**DOI:** 10.1136/annrheumdis-2023-eular.4895

**POS8094**

**POS8095**

**POS8096**
Conclusion: A pre-trained artificial neural network can enable the accurate detection of definite radiographic sacroiliitis relevant for the diagnosis and classification of axSpA close to expert performance. In the present study, the previously trained network showed an excellent ability to generalize data that was completely new to the network. Our results show the potential for classification purposes in multi-center axSpA trials in the future, providing a reproducible and cost-effective tool without unnecessary time delays.

POS0897
THE PERFORMANCE OF COMBINING EYE SIGN AND FUNCTIONAL MAGNETIC RESONANCE IMAGING IN DIAGNOSING PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Diagnostic tests, Systemic lupus erythematosus, Imaging

J. L. H. Shi1. The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: The diagnosis of NPSLE becomes challenging for rheumatologists, both at a diagnostic and therapeutic level. The 1999 ACR criteria had a high sensitivity (91%), but a low specificity (46%) [1].

Objectives: To investigate the alterations of eye sign and functional magnetic resonance imaging (fMRI) in patients with neuropsychiatric systemic lupus erythematosus (NPSLE) and to explore the performance of combining eye sign and MRI in diagnosing NPSLE.

Methods: In phase 1, SLE patients were consecutively recruited Sep 2017 to Sep 2018 including NPSLE patients and non-NPSLE patients. Eye sign examination for bulbar conjunctival microvascular were performed for all SLE patients and fMRI scanning for NPSLE patients. Demographic and clinical data were compared between two groups and to identify potential predictors for NPSLE by using multivariable logistic regression analysis. In phase 2, NPSLE patients in phase 1 were enrolled, and a new diagnostic algorithm including predictors and changed fMRI parameters was designed with the 1999 NPSLE ACR classification as comparison. Expert opinion was considered as golden standard. Double-blind clinical diagnosis from expert were recorded using new algorithm and 1999 ACR classification, respectively. Area under the curve (AUC) under the ROC curve, sensitivity and specificity were calculated and compared between these two diagnostic methods.

Results: 120 SLE patients were recruited (32.9±1.03 years) including 45 NPSLE and 90 non-NPSLE. NPSLE had higher disease activity (reflected as SLEDAI and ESR). Compared with Non-NPSLE group, fMRI showed changed fALFF and fReHo in brain regions relevant to cognition and emotion (p<0.01). Eye sign examination showed NPSLE group had significantly higher scores of ramified loops, vascular tone, microangioma, wound point and had higher total scores than non-NPSLE group (p<0.001). In multivariable logistic analysis, SLEDAI, ramified loop, microangioma, wound point and presence of antiphospholipid antibodies were predictors of NPSLE (Table 1). the AUC of the ACR classification under ROC curve was 0.775, sensitivity was 75.0%, specificity was 80.0% (p=0.002), the AUC of new algorithm under ROC curve was 0.815, sensitivity was 75.0%, specificity was 88.0% (p<0.001) (Figure 1). Conclusion: This proposed new algorithm showed not to be inferior to the 1999 ACR classification and need to be confirmed in further studies.

POS0898 EARLY DETECTION OF ANTI-TNF INDUCED CHANGES IN NEW BONE FORMATION IN PSORIATIC ARTHRITIS PATIENTS BY 18F-FUORIDE PET-CT

Keywords: Imaging, Psoriatic arthritis

J. De Jongh1, G. C. J. Zweerijnen2, R. Hemke2, M. Yaqub2, M. G. H. Van de Sande2, A. Van Kuijk3, A. Voskuyl1, C. J. Van der Laken1. 1Amsterdam UMC, Location VUMc, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 2Amsterdam UMC, Location VUMc, Department of Radiology and Nuclear Medicine, Amsterdam, Netherlands; 3Amsterdam UMC, Location AMC, Department of Radiology and Nuclear Medicine, Amsterdam, Netherlands; 4Amsterdam UMC, Location AMC, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 5Reade, Department of Rheumatology, Amsterdam, Netherlands.

Background: New bone formation in psoriatic arthritis (PsA) can be observed in all musculoskeletal disease domains and can lead to disability due to ankylosis and bridging syndesmophytes [1, 2]. The positive effect of anti-tumor necrosis factor (anti-TNF) therapy on radiographic damage (e.g. erosion and joint space narrowing) is well known, but there are contradictory findings on its effects on new bone formation [3, 4]. Imaging of new bone formation in PsA is pivotal in order to ascertain the extent and potential therapeutic effects on structural changes at an early stage of treatment. Our group recently demonstrated that molecular new bone formation can be observed in all PsA disease domains, using 18F-Fluoride PET-CT scans. Moreover, the ability of this imaging technique to detect early therapeutic effects in ankylosing spondylitis patients was also demonstrated by our group [5].

Objectives: To investigate whether 18F-Fluoride PET-CT scans can detect a change in 18F-Fluoride uptake, reflecting a change in new bone formation, after 12 weeks of anti-TNF therapy in clinically active PsA patients.

Methods: Nine patients (male 4/9, median age 47 (IQR 19)) with PsA fulfilling CASPAR criteria or a clinical diagnosis according to the treating rheumatologist and clinically active disease including ≥1 clinically active enthesitis site were included. In each patient, a whole body 18F-Fluoride PET-CT scan was performed prior to and 12 weeks after starting anti-TNF therapy. Scans were independently assessed for PET-positive lesions (dichotomous) by two readers (blinded for clinical data). Fixed sized volumes of interest were drawn on top of visual PET positive lesions as well as on locations where visual PET positive lesions appeared or disappeared before or after treatment. Standardized uptake values corrected for individual integrated whole blood activity concentration (SUVAUC) were used for quantitative analysis. CT was used for anatomical reference.

Results: Combining all PET-positive lesions of all patients, a total of 153 lesions were observed at baseline (89, 30 and 34 in peripheral joints, entheses and spine, respectively). At week 12, a total of 119 PET-positive lesions were observed (69, 13 and 37 in peripheral joints, entheses and the spine, respectively). Grouping all lesions of all patients, there was a decrease in the mean SUV AUC between baseline (1.578, SD 0.99) and week 12 of anti-TNF treatment (1.230, SD 0.85) (Figure 1A). Similar results were observed when grouping all lesions of all patients for separate disease domains. Mean SUV AUC changes between baseline and 12 weeks were -0.294 (SD 0.88), -0.357 (SD 0.69) and -0.300 (SD 0.67) for respectively peripheral joints (Figure 1B), entheses (Figure 1C) and the spine (Figure 1D).

Conclusion: 18F-Fluoride PET-CT detected a change in new bone formation in PsA domains during anti-TNF therapy as early as 12 weeks post-treatment. The data point at a mean decrease of new bone formation in peripheral joints, entheses and axial skeleton.

SPECIFICITY OF SALIVARY GLAND ULTRASOUND IN THE DISCRIMINATION OF PRIMARY SJÖGREN’S SYNDROME FROM UNDIFFERENTIATED CONNECTIVE TISSUE DISEASES

Keywords: Imaging

M. Djenne1a, T. Arexi1, S. Slimani2, H. Imene3, A. Ittiane1, 1University Mouloud Mammeri, Department of Medicine, Tizi Ouzou, Algeria; 2University of Batna, Department of Medicine, Batna, Algeria

Background: Recently, compelling data have been published on the value of salivary gland ultrasound (SGUS) in differentiating between primary Sjögren’s Syndrome (SS) from non-immune-mediated sicca syndrome. Limited data are available regarding the diagnostic accuracy of SGUS to distinguish SS from undifferentiated connective tissue diseases associated with sicca syndrome.

Objectives: The aim of this study was to evaluate the power of SGUS to distinguish patients with SS from those with xerostomia and/or xerophthalmia and suffering from undifferentiated connective tissue diseases.

Methods: Our cross-sectional study consecutively recruited 95 patients with either SS (according to the American European Consensus Group criteria) or undifferentiated connective tissue diseases associated with sicca syndrome. Immunological assessment and salivary gland biopsies were performed in all patients. Ultrasonography of the parotid and submandibular glands on both sides were assessed for size, parenchymal echogenicity, and inhomogeneity, by the same blinded rheumatologist. A second ultrasound reading was performed blinded by another rheumatologist, with inter-observer Kappa calculation. Ultrasound abnormalities of the salivary glands were graded according to the OMERACT score ranging from 0 to 3 (threshold ≥2).

Results: The study included 95 patients; 51 with SS and 44 with undifferentiated connective tissue disease. Patients with SS showed a higher SGUS score compared with those with xerostomia with sicca syndrome [mean 1.69 (SD=1.17) versus 0.18 (SD=0.44), P < 0.0001]. The SGUS threshold showed a sensitivity of 60%, a specificity of 98%, a positive predictive value of 97% and a negative predictive value of 67% for the diagnosis of SS. A significant correlation was also found between the SSUS score and the minor salivary gland biopsy/focus score (r=0.64, P<0.0001). Finally, the inter-observer Kappa coefficient ranged from 0.61 to 0.70.

Conclusion: Our study confirmed the good sensitivity and high specificity of SGUS in differentiating SS from other undifferentiated connective tissue diseases with sicca syndrome.

CAN B-MODE OCULAR ULTRASOUND ASSESS VITRITIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS?

Keywords: Ultrasound, Inflammatory arthritis, Uveitis

J. A. Mendonça1, L. Eduardo Pedri2, F. Andrade3, L. Biselli3, L. B. Nucci4

1Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences and Rheumatology/Ultrasoundography Service, Sumaré, Brazil;
2Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences and Rheumatology/Ultrasoundography Service, Campinas, Brazil;
3Pontifical Catholic University of Campinas, Clinical Center, Egas Moniz Health Alliance Academic Clinical Center, Aveiro, Portugal;
4Pontifical Catholic University of Campinas, Ophthalmology Service, Campinas, Brazil;
5Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences/Statistics Service, Campinas, Brazil

Background: Vitritis is the presence of cellular infiltration in the vitreous body resulting from inflammation of the vitreous cavity itself or from the extension of the anterior chamber inflammatory process[1]. Uveitis is the most frequent extra-articular manifestation of axial spondyloarthritis and psoriatic arthritis, and may occur in any uveal topography[2]. B-mode ultrasound can be useful for confirming uveitis, especially in those conditions in which there is opacification of the light-conducting medium and the vitreous cavity and the rest of the globe cannot be visualized by ophthalmological examination[3]. In the case of vitritis, the vitreous appears on the ultrasound screen in the form of thin, confluent and mobile images[4].

Objectives: To detect the presence of vitritis in patients with axial spondyloarthritides and psoriatic arthritis using a B-mode ocular ultrasound and comparing it with the slit lamp ophthalmologic examination.

Methods: Observational and cross-sectional study with 6 patients with non-radiographic axial spondyloarthritis according to the ASAS criteria; 24 with radiographic axial spondyloarthritis according to the modified New York criteria and 34 with psoriatic arthritis according to the CASPAR criteria, selected for convenience between the months of August and December 2021, from the Rheumatology outpatient clinic of the Pontifical Catholic University of Campinas Hospital. One hundred and twenty-six eyes were evaluated by an ophthalmologist by slit lamp biomicroscopy. B-mode ocular ultrasound machine (EsaoteSpA, São Paulo, Brazil) was performed with a high frequency linear probe of 12MHz. A total of 127 eyes were evaluated, categorizing vitreitis semi-quantitatively through the intensity of echoviteous in grades 0 (absent), 1 (mild), 2 (moderate) and 3 (severe) (Figure 1). Sensitivity, specificity, negative (NPV) and positive (PPV) predictive values and the ROC curve were calculated for B-mode ultrasound in relation to the ophthalmological evaluation.

Results: The mean age of patients with axial spondyloarthritis was 46.5±13 years, with a BASDAI of 4.10±2.84. The mean age among patients with psoriatic arthritis was 55.2±12.5 years, with a DAPSA of 24.27±22.15. Ophthalmic examination detected vitritis in 3.33% of the eyes. B-mode ultrasound identified grade 0 echoviteous in 39.37% of the eyes; grade 1 in 25.98%, grade 2 in 10.95% and grade 3 in 25.98%.

Conclusion: B-mode ultrasound showed an excellent negative predictive value for detecting vitritis, constituting an important complementary tool in the evaluation of uveitis in patients with axial spondyloarthritis and psoriatic arthritis.

**Objectives:** To analyze the disease phenotype of patients with anti-Ro52 and/or anti-Ro60.

**Methods:** Multicenter, cross-sectional study of anti-Ro52 and/or Ro60 positive patients followed at 10 Rheumatology centers from January 2018 until December 2021. Patients were categorized into 3 groups: group 1 (Ro52+/Ro60−); group 2 (Ro52−/Ro60+); group 3 (Ro52+/Ro60+). Antinuclear antibodies were evaluated by indirect immunofluorescence assay and further screened for anti-extractive nuclear antigen (ENA) antibodies. Demographics and clinical data were compared between the 3 groups, by patients’ medical chart review. Univariate analysis was performed using chi-square, Fisher’s exact or Kruskall-Wallis test. Subsequently, the Bonferroni test was used to identify intergroup differences (level of significance: p<0.0167). Univariate logistic regression was used to calculate the odds ratio with a 95% confidence interval (CI).

**Results:** We included 776 patients [female: 83.1%; median age: 59 (46-71) years]. Groups 1, 2 and 3 comprised 31.1%, 32.6%, and 36.3% of the patients, respectively. Characteristics of the groups are presented in Table 1. Anti-Ro52 alone is more frequently associated with non-rheumatic diseases, older age, and men (p<0.05). Among patients with CTD, the diagnosis of systemic lupus erythematosus is 3 and 2 times more prevalent in groups 2 and 3, respectively, than in group 1 [OR 2.8 (95% CI 1.60, 4.97), p<0.001; OR 2.2 (95% CI 1.28, 3.86), p=0.007]. In group 2, the diagnosis of undifferentiated connective tissue disease is more frequent than in the other groups. The presence of isolated Ro52+ is more frequently associated with inflammatory myositis than in group 2 [OR 0.09 (95% CI 0.01, 0.33), p<0.001] or group 3 [OR 0.08 (95% CI 0.01, 0.29), p<0.001]. Group 1 was also more frequently associated with arthritis (p=0.006), interstitial lung disease (p=0.002), and myositis (p=0.009).

**Conclusion:** Anti-Ro52+ alone is frequently found in patients with non-rheumatic diseases. In addition, anti-Ro52+ is also prevalent in patients with CTD and associated with clinical phenotypes that are different from anti-Ro60+.

**Conclusion:** The results of our study suggest that the involvement of the venous system is diffuse and generalized in BD, and demonstration of venulitis might help diagnose the disease. Further studies are needed to elucidate prognostic role of wall thickening, venulitis, in terms of anticipation of future thrombosis and treatment response.

Methods: Observational retrospective study involving the Rheumatology Departments of Centro Hospitalar Universitário Lisboa Norte (CHULN), Lisbon-Portugal, and the Nuffield Orthopaedic Centre (NOC), Oxford-UK. We included patients with biopsy-proven GCA, always due to the lack of information regarding the demographics, clinical manifestations at disease presentation, and therapies were collected. Cranial symptoms included headache, temporary or permanent loss of vision, diplopia, blurred vision, jaw or tongue claudication, scalp tenderness or paraesthesia, stroke, or transient ischemic attack (TIA).

Results: We included 230 patients, 139 (60.4%) from the NOC and 91 (39.6%) from CHULN. One hundred and thirty-six (59.1%) patients were females, and the mean ± standard deviation age at diagnosis was 75.3 ± 8.5 years. The ultrasound was performed after ten days of treatment with prednisolone ≥30mg/day in 70/230 (30.4%) patients. The presence of halo sign in the TAs was found in 207/230 (90.0%) patients, in whom AXs involvement was positive. The AXs ultrasound pattern presented, 173/230 (75.2%) patients had positive TAs and negative AXs ultrasound, 23/230 (10.0%) had negative TAs and positive AXs ultrasound, and 34/230 (14.8%) had both positive TAs and AXs ultrasound. Cranial symptoms were reported in 207/230 (90.0%) patients, in whom AXs involvement was ultrasound was detected in 43/207 (20.8%) cases. Concerning only the patients with negative TAs and positive AXs ultrasound, 13/23 (56.5%) patients had cranial symptoms. Headache was reported in 10/23 (43.5%), visual symptoms in 6/23 (26.1%), jaw or tongue claudication in 4/23 (17.4%), scalp tenderness or paraesthesia in 4/23 (17.4%), and stroke or TIA in 1/23 (4.3%) patients. Patients were on glucocorticoid treatment at the time of diagnosis, i.e., the presence of a non-compressible halo sign in the TAs or AXs. Information regarding the demographics, clinical manifestations at disease presentation, and therapies were collected. Cranial symptoms included headache, temporary or permanent loss of vision, diplopia, blurred vision, jaw or tongue claudication, scalp tenderness or paraesthesia, stroke, or transient ischemic attack (TIA).

Conclusion: Axial involvement in GCA is frequent, affecting around 14.5% of the patients at diagnosis. The additional assessment of the AXs improved the ultrasound diagnostic sensitivity by 10% compared to only assessing the TAs. Patients with AXs involvement were reported to have cranial symptoms in 43/57 (75.4%) cases. More than half of the patients with negative TAs and positive AXs ultrasound presented with cranial symptoms. Our results support the need to assess the AXs in patients with suspected GCA, regardless of the presence or absence of cranial symptoms.

POS0906
ULTRASONOGRAPHY AND FDG-PET/CT FOR SUSPECTED POLYMYALGIA RHHEUMATICA: DIAGNOSTIC PERFORMANCE IN TREATMENT-NAIVE VERSUS ALREADY TREATED PATIENTS

Keywords: Diagnostic tests, Imaging, Musculoskeletal

POS0905
AXILLARY ARTERIES ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS WITH PREDOMINANTLY CRANIAL SYMPTOMS

Keywords: Diagnostic tests, Imaging, Vascular

Disclosure of Interests: None Declared. DOI: 10.1136/annrheumdis-2023-eular.3307
Background: Polymyalgia rheumatica (PMR) is a common rheumatic, inflammatory disease in the elderly. Traditionally, the diagnosis is based on clinical and laboratory findings, which are not specific for PMR. Although, which patients initially respond well to glucocorticoid (GC) treatment, a refractory or relapsing disease course is not uncommon and may cause doubt about the initial diagnosis. This usually prompts additional diagnostic evaluation for PMR with imaging tools such as ultrasonography and FDG-PET/CT, usually after GC tapering. However, it is unclear whether these tests perform equally well in patients already treated under the presumed diagnosis of relapsing or refractory PMR, when compared to treatment-naive patients, suspected of new PMR.

Objectives: To compare the diagnostic accuracy of ultrasonography and FDG-PET/CT for PMR in treatment-naive and already treated patients.

Methods: Retrospective study including 144 consecutive patients that were referred to the Rheumatology and Clinical Immunology department for suspected PMR, including 63 treatment-naive patients, and 81 already treated patients with or without still ongoing treatment. Patients were referred by general practitioners (n=107) or other medical specialist. Bilateral ultrasonographic evaluation of the shoulders and hips was performed in 135 patients. The presence of biceps tenosynovitis, subacromial bursitis, glenohumeral synovitis, hip synovitis, and trochanteric bursitis was assessed. A sum score of the latter abnormalities was constructed (score range 0-10), and termed total ultrason score. FDG-PET/CT from skull to upper legs was performed in 72 patients. FDG uptake was visually scored at 12 key sites in order to calculate the Leuven PMR-PET score (score range 0-24) [1,2]. The final clinical diagnosis at 6 months was the reference standard.

Results: A clinical diagnosis of PMR was made in 94/144 (65%) patients. The provisional ACR/EULAR criteria for PMR were fulfilled in 67/94 (71%) patients with PMR and in 19/50 (38%) patients without PMR. More specifically, PMR was diagnosed in 42/63 (67%) treatment-naive patients and 52/81 (64%) already treated patients. Among the already treated patients, 24 patients were still on GC treatment during the ultrasound scan (median prednisolone dose 6.25 mg daily, range 1.25-30), while 2 patients were taking methotrexate (n=1) or leflunomide (n=1). Only 2 patients were on GC treatment during the FDG-PET/CT scan (prednisolone dose 1 and 2.5 mg), while 1 patient was treated with leflunomide. The total ultrasound score and Leuven PMR-PET score showed good diagnostic accuracy in treatment-naive patients as indicated by the AUC in the ROC analysis (Table 1). The diagnostic accuracy of the total ultrasound score was poor in patients that had already been treated, even when GC treatment had been fully tapered. In contrast, the diagnostic accuracy of FDG-PET/CT remained good in already treated patients.

Conclusion: FDG-PET/CT shows equal diagnostic accuracy for already treated PMR as for treatment-naive PMR, if GC therapy is fully tapered. However, ultrasonography for suspected PMR is best performed before initiation of treatment. A simple sum score of inflammatory lesions in the shoulders and hips aids the interpretation of ultrasonography in PMR.

POS0097 ULTRA-HIGH FREQUENCY ULTRASOUND TO ASSESS SKIN INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: PRELIMINARY DATA FROM A MONOCENTRIC COHORT

Keywords: Skin, Ultrasound, Systemic lupus erythematosus

C. Cardelli1,2, V. Signorini1, G. Granieri2, C. Stagnaro1, L. Carl1, F. Ferro1, E. Elefante1, D. Zucchi1,2, D. Trentin1, G. Monaco1, C. Tani1, V. Dini2, M. Romanelli2, M. Mosca1,1. University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 2University of Siena, Department of Medical Biotechnologies, Siena, Italy; 3University of Pisa, Dermatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy

Background: The assessment of cutaneous involvement in Systemic Lupus Erythematosus (SLE), particularly the differential diagnosis between active lesions and damage, might be a challenge for the clinicians. Ultra-high frequency ultrasound (UHFUS), with a sub-millimeter resolution, is a promising tool in the evaluation of superficial structures. In recent years its use has grown in the field of dermatology, where UHFUS finds application in the study of normal anatomy, differentiation of cutaneous lesions (bullous and inflammatory disease), diagnosis of skin malignancies and pre-surgical mapping, increasing diagnostic sensitivity and accuracy in guiding medical and surgical therapies.

Objectives: The aim of the study was to explore a possible role of UHFUS assessment in the evaluation of skin involvement in a monocentric cohort of SLE patients and to evaluate the relationship with patients’ perception of their skin disease.

Methods: Consecutive adult SLE patients (1997 ACR criteria) regularly followed at our Lupus Clinic were prospectively enrolled during a scheduled outpatient visit in presence of skin lesions. Demographical, clinical, laboratory and treatment data were collected at enrolment. Disease activity and organ damage were evaluated with the SLEDAI-2K and SLECC-DI, respectively. Clinical assessment of skin lesions was done by an experienced rheumatologist using the Cutaneous LE Disease Area and Severity Index (CLASI); at the same time, UHFUS evaluation of skin lesions was performed with a 70 MHz probe by an experienced dermatologist. The Skindex-16 questionnaire was used to assess the impact of the skin involvement on patients’ quality of life.

Results: We included 70 assessments in 55 SLE patients with skin lesions (5/55 evaluated twice, 5/55 three times). Cutaneous disease subtypes were distributed as follows: acute 37.5%, subacute 12.5%, chronic 50.0%. The characteristics of the cohort are shown in Table 1. The most frequent UHFUS alteration was the presence of power Doppler (51/70, 72.9%), followed by dermal oedema (37/70, 52.9%), dermal inhomogeneity (33/70, 47.1%), follicular plugging (32/70, 45.7%), vascular ectasia (27/70, 38.6%) and thinning of the epidermis (10/70, 14.3%). The CLASI activity score was significantly higher in cutaneous areas with power Doppler signal (p=0.032). Dermal oedema was also found to be associated with...
higher CLASI activity scores, considered both globally (p<0.001) and at the level of the US-evaluated region (p<0.002), and with higher damage scores of the evaluated area (p<0.034), while vascular ectasia was only associated with higher damage scores of the evaluated area (p=0.036). Skinex-16 symptoms subscale scores were significantly higher in patients with thinning of the epi- dermis (p=0.01) and dermal inhomogeneity (p=0.049). Regarding the subtype of cutaneous involvement, vascular ectasia was significantly more frequent in chronic cutaneous LE (p<0.029), while no other UHFUS alterations were found to differ between the three groups.

Conclusion: Through preliminary, our data seem to suggest UHFUS as a promising tool not only for assessing skin involvement in SLE, but also for monitoring disease activity over time with a view to optimising the management of these patients.

NAILFOLD CAPILLAROSCOPY FINDINGS OF INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF)

Keywords: Lungs, Imaging

S. H. Lee1, H. K. Min2, H. R. Kim1. 1Konkuk University School of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Objectives: We evaluated nailfold capillaroscopy (NFC) of interstitial pneumonia with autoimmune features (IPAF) and compared it with that of patients with CTD-ILD and idiopathic interstitial pneumonia (IIP).

Methods: Patients with newly diagnosed as ILD were evaluated using NFC. Baseline demographic, clinical, serological, and high-resolution CT findings were collected. NFC was semi-quantitatively scored with six domains ranging from 0 to 18. In addition, the overall patterns (scleroderma/non-scleroderma patterns) were determined.

Results: A total of 81 patients (31 with CTD-ILD, 18 with IPAF, and 32 with IIP) were included. The non-specific interstitial pneumonia pattern was the most common IBD pattern in the CTD-ILD and IPAF groups, whereas the usual interstitial pneumonia pattern was the most common in the IIP group. The semi-quantitative score for NFC of the CTD-ILD group was higher than that of the IPAF or IIP groups (5.8 vs 4.2 vs 3.0, p < 0.001, respectively). Giant capillaries and haemorrhages were more frequently present in the CTD-ILD and IPAF groups than in the IIP group.

A scleroderma pattern was present in 27.8% of the IPAF group, whereas none of the IIP patients showed a scleroderma pattern.

Conclusion: NFC findings may be useful in classifying patients with ILD into CTD-ILD/IPAF/IIP.

POS0909

IS IT NECESSARY TO STOP NOVEL ORAL ANTICOAGULANT THERAPY PRIOR TO MUSCULOSKELETAL ULTRASOUND GUIDED INTERVENTIONAL MANEUVERS?

Keywords: Comorbidities, Ultrasound, Inflammatory arthritis

M. Micu1, A. Duju2, A. Micu3. 1Rehabilitation Clinical Hospital Cluj Napoca, Rheumatology Division, Cluj Napoca, Romania; 2Iuliu Hâțieganu University of Medicine and Pharmacy Cluj-Napoca, Romania, Department of Medical Biochemistry, Cluj Napoca, Romania; 3Iuliu Hâțieganu University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania

Background: Anticoagulation is common in patients undergoing arthrocentesis or joint/periarticular injections. Previous retrospective studies have established the safety of continuing anticoagulation with Novel Oral Anticoagulant Therapy (NOAC) when performing such kind of interventional maneuvers [1]. Indeed, ultrasound guided interventional maneuvers have shown a superior safety profile compared to blind anatomical maneuvers [2].

Objectives: To evaluate the post-procedural bleeding complications in patients diagnosed with inflammatory/ degenerative rheumatologic pathology.

Methods: Consecutive patients diagnosed with inflammatory/ degenerative rheumatologic pathology requiring interventional articular/ periarticular maneuvers were prospectively recruited. Patients were divided in two groups – Group 1 treated with NOACs and Group 2 (control group) without anticoagulation. NOAC therapy was administered in a continuous regimen prior to the interventional maneuver, in therapeutic regimens dictated by the underlying anticoagulation indication. Demographics, laboratory analysis, systemic medication, local administered medication (corticosteroids/ viscosupplementation), interventional maneuver location, type of needle, the occurrence/ absence of bleeding accidents in the anatomical structures submitted to needle penetration were recorded. The written informed consent was obtained. Post-procedural control was performed at 30 minutes, 48 hours and 7 days.

Results: Results are presented in Table 1. No articular/ intra- tendon sheath/ bursa or muscular bleeding event occurred in patients treated with NOAC regardless of their type and dosage, local medication administration/ needle size/ location and number of interventions per individual. Several patients in both groups developed small superficial ecchymoses at injection site.

Table 1. Demographics, laboratory analysis, systemic medication, interventional maneuver location, type of needle, the occurrence/ absence of bleeding accidents.

*SASDb = subacromial subdeltoid bursa, GFR=glomerular filtration rate

Conclusion: Our results suggest that NOACs are safe to be used in a continuous regimen prior to joint/periarticular ultrasound guided injections, even in combination therapy with aspirin. The use of lower gauge needles, chosen for vicosupplementation therapy, was not burdened with adverse effects on the procedural outcome.

A MULTIPLEX RT-QPCR KIT FOR EXPRESSION ANALYSIS OF INTERFERON-STIMULATED GENES AS A USEFUL TOOL FOR MOLECULAR STRATIFICATION IN LUPUS AND OTHER AUTOIMMUNE DISEASES

Keywords: Validation, Diagnostic tests, Systemic lupus erythematosus

J. Qian1, L. Lu1, Z. Cao2, Q. Fu1. 1Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Department of Rheumatology, Shanghai, China; 2Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Institute of Molecular Medicine, Shanghai, China

Background: It is recognized that the expression of interferon (IFN)-stimulated genes (IFN signature) plays a significant role in several autoimmune diseases (AIDs) [1], such as systemic erythematosus lupus (SLE), idiopathic inflammatory
myopathies (IIM) and rheumatoid arthritis (RA). A quick and ready-to-use method to differentiate IFN activation state is clinically needed.

**Objectives:** This study aimed to conduct analytical validation of the Multiplex ISGs RT-qPCR Kit in clinical practice

**Methods:** We designed a multiplex RT-qPCR method to provide IFN score covering both type I IFN and type II IFN by simultaneously detecting the expression of 3 IFN stimulated genes (ISGs), IFI44, MX1(type I ISGs), and IRF1(type II ISG), relative to one housekeeping gene (HPRT1). Measurements were performed on mRNA extracted from the peripheral blood cells of patients with multiple AIDs. The relative expression of each target gene (T/R) was calculated via 2^-ΔΔCT. The T/R of each target gene was then normalized as the following: T/R - Mean H1/ SD HC. IFN score was calculated as the mean of the normalized T/R of three target genes. Scores higher than the mean of HC plus two SD were designated IFN score high; otherwise, IFN score low. Analytical validation was performed to assess compliance rate, accuracy and method detection limit.

**Results:** Significantly elevated IFN scores were found in SLE(n=116), IIM(n=118), and RA(n=17) compared to other AIDs and HC. Four distinct subpopulations of SLE patients were observed: Thirty-five percent of SLE patients exhibited elevation of all three genes, indicating both type I and type II IFN pathways were activated. 44% of SLE patients had elevated expression of type I ISGs but no change in the type II ISG suggesting only type I IFN pathway was activated. 15% SLE patients presented no elevated expression of ISG gene. And 6% SLE patients only showed increased expression of IRF1 without overexpression of other 2 Type I ISGs, suggesting they probably only had type II IFN pathway activated. We repeated the tests. The compliance rate was 100% and accuracy was 100% with a CV of 0.36%. The method detection limit was 0.61 ng/μL.

**Conclusion:** Using the Multiplex ISGs RT-qPCR Kit, we assessed the IFN score in multiple AIDs. The analytical validation of the kit reveals that it is a reliable, reproducible diagnostic tool that will be useful in clinical practice but may require confirmation in larger-scale trials.

**SARCOPENIA IN SPONDYLOARTHRITIS. ULTRASOUND EVALUATION**

**Keywords:** Spondyloarthritis, Ultrasound, Sarcopenia

C. Soto1, C. A. Lozada Perez2, A. Angeles-Acuna1, S. Y. Solorzano Flores1, F. Carranza-Enríquez1, C. Vega1, C. Pineda.1 Instituto Nacional de Rehabilitación, Departamento de Reumatología, Mexico city, Mexico

**Background:** Spondyloarthritis are a group of chronic inflammatory rheumatic diseases that share clinical and imaging characteristics. Sarcopenia is characterized by loss of muscle mass and function associated with impairment of quality of life and adverse outcomes such as fractures and death. Patients with Spondyloarthritis had a prevalence of up to 25.7% of sarcopenia. The available imaging techniques for the detection of low muscle quantity and quality are: dual-energy X-ray absorptiometry (DXA), bioelectrical impedance analysis (BIA), and recently muscular ultrasound (US). Ultrasound estimate muscle quantity using prediction equations based on muscle thickness that have shown to be highly reliable in healthy population. Among the models used, the following equations are applicable in different ethnicities to predict muscle mass Abe 2018, Barbosa Silva 2021, Tang 2022.

**Objectives:** To evaluate the prevalence of sarcopenia in Spondyloarthritis and to determine which of the three ultrasonographic predictive models correlates best with BIA and DXA in our population.

**Methods:** Observational, cross-sectional study. We included 42 patients with spondyloarthritis (according to ASAS criteria for ankylosing spondylitis or CASPAR criteria for psoriatic arthritis). Appendicular skeletal muscle mass (ASM) was evaluated by DXA and predicted by BIA and US. We performed a US examination with a GE LOGIQ e, equipped with a broadband linear probe to measure muscle thickness (MT) at seven sites. Based on ultrasound prediction models, we use age, sex, height, and MT to estimate ASM (Abe 2018, Barbosa-2021, and Tang-2022). A bivariate analysis was performed to assess the differences between patients with and without decreased ASM. Pearson’s correlation coefficient was calculated to evaluate the correlation of the ultrasonographic predictive models with DXA and BIA. Finally, a ROC curve analysis was performed to determine the area under the curve of the models.

**Results:** We included 42 patients, composed mainly of men (24/42, 57.1%), with ankylosing spondylitis (AS) in 35 (83.3%) and psoriatic arthritis (PsA) in 7 (16.7%). The prevalence of sarcopenia was about 33% (10/14 sarcopenia y 4/14 severe sarcopenia). When comparing patients with and without decreased ASM, differences were only found in ultrasonography measurements of the quadriceps and anterior tibial muscles (p=0.003 y 0.00). On the other hand, the ultrasound prediction models had a moderate to strong correlation with DXA and BIA (0.80, 0.87, 0.53 and 0.68, 0.74, 0.66 for Abe-2018, Barbosa-2021, and Tang-2022). Nevertheless, in the ROC curve, the ABE-2018 model expresses a better diagnostic performance (AUC 0.80 p=0.002).

**Conclusion:** Results indicated a low ASM in 30% of the patients with Spondyloarthritis (sarcopenia 24.4%, severe sarcopenia 9.8%). This study supports the use of ultrasound and shows a good correlation with DXA and BIA for ASM evaluation in Spondyloarthritis, particularly with the Abe-2018 predictive model.

**LOW ADDITIVE VALUE OF A REPEAT MRI EXAMINATION OF THE SACROILIAC JOINTS WHEN THE FIRST MRI IS INCONCLUSIVE**

**Keywords:** Imaging, Inflammatory arthritis, Spondyloarthritis

I. Eshed1, T. Goitein1, M. Lidar1, 1Sheba Medical Center, Diagnostic Imaging, Ramat Gan, Israel; 1Sheba Medical Center, Rheumatology Unit, Ramat Gan, Israel

**Background:** Diagnosing sacroiliitis on MRI of the sacroiliac joints (SIJ) is not always straightforward. It is common practice in inconclusive cases to repeat the MRI after a variable period of time with an expectation that more conclusive acute/structural lesions will develop and allow for an irreversible diagnosis of sacroiliitis.

**Objectives:** To evaluate the diagnostic utility of a repeat SJU MRI following an initial inconclusive MRI examination.

**Methods:** Subjects with >1 SJU MRI examinations, where the index scan was inconclusive for sacroiliitis and ≥ 6 months’ interval has elapsed between scans, were included. Repeat scans were evaluated for the presence of structural/acute SIJ lesions and were accordingly diagnosed with either sacroiliitis or another applicable diagnosis. Clinical data was extracted from the patients’ clinical files and by a telephone questionnaire. Diagnoses and scores were compared between index and follow-up examinations (t test).

**Results:** 71 subjects were included in the study; 77.4% females, mean age 41.0±15 years. Mean time interval between exams 30.4± 25.24 months. 12 subjects performed >2 scans. Clinical information was available in 63 subjects (86%) and is summarized in Table 1. In only two subjects (2.81%), both females, MRI diagnosis changed from inconclusive to definite sacroiliitis on the follow-up scan; a 41-year-old patient that had inflammatory back pain for two years prior to the index MRI, had peripheral arthritis but no family history of SpA and a 39-year-old patient with inflammatory back pain since the age of 23 years and an elevated CRP but no family history of SpA or other clinical rheumatic involvement. Final diagnosis after the 2nd MRI was osteitis condensans ili in 29 patients, DISH in 3 patients, degenerative changes in 6 patients (two accompanied by enthesitis) and enthesitis in 1 patient. In 10 patients (14.1%) diagnosis was still inconclusive after the 2nd MRI examination. No major abnormality was found in the follow-up MRI examination in 20 subjects. None of the subjects with >2 scans, had evidence of sacroiliitis in any of the following MRI examinations.

**Conclusion:** Repeating SJU MRI examination when index MRI is inconclusive is of minimal additive value. When MRI findings are inconclusive, decision making should be based on clinical data.

ULTRASONOGRAPHIC EVALUATION OF ENTHESEAL FIBROCARTILAGE IN PATIENTS WITH PSORIATIC ARTHRITIS, HEALTHY CONTROLS AND ATHLETES: A COMPARISON STUDY

Keywords: Enthesitis, Psoriatic arthritis

F. M. Perrotta1, S. Scriffignano1, M. Ronga2, E. Lubrano1,1Università degli Studi del Molise, Medicina e Scienze della Salute, Campobasso, Italy;1University of Piemonte Orientale, Health Sciences, Novara, Italy

Background: Enthesitis is the hallmark Psoriatic Arthritis (PsA), with the enthesal fibrocartilage (EF) found to be the possible target tissue of inflammation [1]. With the development of feasible and more accurate imaging modalities, the in vivo study of this important tissue has become more precise.

Objectives: The aim of this study was: 1) to evaluate the EF at Achilles tendon insertion by using power Doppler ultrasound (PDUS) in PsA 2) to assess the intra and inter-reader reliability in the evaluation of EF thickness 3) to compare EF thickness of healthy controls (HC) and athletes; 4) to evaluate the association of EF abnormalities with other enthesal abnormalities and disease activity and functional indices in PsA.

Methods: Consecutive PsA patients attending our unit with age < 50 years were asked to participate. HC and agonist athletes (basketball and soccer players with a minimum of 10 hours training per week) were enrolled as control group. Bilateral PDUS evaluation of Achilles tendons was performed in order to evaluate the EF in all patients and controls. EF was defined as the thickness of the anechoic layer just above the cortical bone and was measured at its thickest point in the longitudinal scan, as previously described [2]. All PsA patients underwent a complete clinical examination.

Results: 30 PsA patients, 20 HC and 40 athletes were enrolled. Female/male ratio was balanced among the three group. Median age (IQR) was higher in PsA patient (49; 41-54) than HC (26; 21-29) and athletes (24; 21-27). Four (13.3%). No patients had clinical heel enthesitis. Median (IQR) EF thickness between PsA, athletes and HC was 0.035 (0.03-0.04) cm, 0.035 (0.03-0.04) cm and 0.03 (0.02-0.04) cm respectively (p=0.05 between PsA and HC; Kruskal-Wallis analysis, see Figure 1). The intra-reader reliability was excellent [intraclass correlation coefficient-ICC (95% confidence interval-Cl) of 0.91 (0.88-0.95) and the inter-reader reliability good [ICC (95% CI) of 0.80 (0.71-0.86)]. At PDUS, no statistically significant differences were found in enthesal abnormalities. However, 3 PsA patients showed erosions at enthesal site in respect to HC and athletes which did not show erosive changes. We did not find correlations between EF thickness and BMI, age, disease duration, disease activity (assessed by DAPSA), LEI and impact of disease (assessed by PsAID) and duration of sport activities in athletes. A trend toward a correlation between EF thickness and body weight was found (Table 1). Assessment of EF was feasible with a mean time of 2 minutes.

Conclusion: The assessment of EF is a feasible and reproducible test. Furthermore, our data suggest an increased thickness of EF in PsA patients in respect to HC with similar values in respect to agonist athletes and may open the way to further large studies on this peculiar aspect.

Disclosure of Interests: Fabio Massimo Perrotta Speakers bureau: Lilly, Novartis, Abbvie; Silvia Scriffignano: None declared, Mario Ronga: None declared.
Background: Cholesterol efflux capacity (CEC) measures the ability of high-density lipoprotein (HDL) to remove cholesterol from arterial wall macrophages upon interaction with membrane transporter proteins and reduce the lipid content of atherosclerotic plaques. CEC inversely associated with cardiovascular risk in general patients independently of HDL levels. CEC through the ATP-binding-cassette G1 (ABCG1) membrane transporter is impaired in RA, yet, its relationship to atherosclerosis and cardiovascular risk is unknown.

Objectives: We here evaluated associations of ABCG1-mediated CEC with coronary atherosclerosis burden, plaque progression and incident cardiovascular event risk in RA.

Methods: Coronary atherosclerosis was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 83.6±4.0 months. ABCG1-mediated CEC was measured in Chinese hamster ovary cells, not transfected or transfected with ABCG1 gene, as per - angiography in 140 patients without cardiovascular disease and reassessed in.

Results: Mean (standard deviation [SD]) of ABCG1 was 4.71 (0.92)%). At baseline, ABCG1 inversely associated with likelihood of extensive atherosclerosis (≥5 plaques) (odds ratio 0.50 [95% CI 0.29-0.88]) and numbers of partially-calcified (rate ratio [RR] 0.71 [95% CI 0.53-0.94]) and low-attenuation plaques (RR 0.83 [95% CI 0.43-0.91]) independently of ASCVD score and statin use. There were no main effects of ABCG1-CEC in adjusted plaque progression models. However, higher ABCG1-CEC predicted decreased noncalcified and calcified plaque progression exclusively in patients with higher time-weighted mean prednisone dose (Figure 1A,B). Furthermore, ABCG1-CEC inversely associated with progression of partially-calcified plaque at lower time-averaged CRP levels (Figure 1C). ABCG1-CEC did not have a main effect on cardiovascular event risk after adjusting for ASCVD score. However, higher ABCG1 associated with lower risk in patients with any versus no prednisone exposure during follow-up (Figure 1D,G), ≥1 versus no noncalcified plaques (Figure 1E,H), and low (<median) versus higher baseline CRP (Figure 1F,I) after adjustments including for ASCVD score (p-for-interaction=0.008, 0.021 and 0.033 respectively).

Conclusion: ABCG1-mediated CEC inversely associated with coronary plaque burden and number of high-risk plaques at baseline. It further predicted decreased plaque progression conditionally on cumulative inflammation and prednisone dose. Notably, ABCG1-mediated CEC inversely associated with cardiovascular risk specifically in prednisone users, patients with noncalcified plaques at baseline and those with lower inflammation.

Background: Active sacroiliitis represent the radiological hallmark of Ankylosing Spondylitis (Ax-SPA) and manifest as low back pain accompanied by morning stiffness (MS). The pain at rest as well as MS represent the main symptoms that impair patients’ quality of life. The treatment of Ax-SPA rely on non steroid anti-inflammatory drugs (NSAIDs), monoclonal antibodies as Anti-TNF-α, anti interleukine-17/23 and, recently, on Janus Kinase Inhibitors; such compounds modify the disease natural history and reduce inflammation, thus restoring patient’s well being and quality of life. However, despite a full treatment regimen, sometimes it is not possible to reach a low disease activity or remission.

Objectives: In rheumatological practice, corticosteroids (GCs) injections are successfully exploited in the every-day scenario to treat oligo-articular inflammatory disorders. In this context, we decided to evaluate the long-term efficacy of ultrasound-guided sacroiliac joint injections (US-SIJIs) of GCs in the treatment of active sacroiliitis and to understand whether local therapy has a role in the management of active sacroiliitis.

Methods: We enrolled patients affected by Ax-SPA with active sacroiliitis from our outpatient clinic. Some were treated with an US-SUI when starting a biological disease modifying rheumatic drug (bDMARD) while others were treated with conventional therapy (bDMARD + NSAIDs) and used as controls. Variables such as age, gender, disease duration, type of bDMard, visuo-analogic pain scale (VAS) and MS were collected at baseline. VAS and MS were collected at each follow up visit that were scheduled at 24 and 48 hours, then after 7 days, 14 days, 1, 3, 6, 9 and 12 months. Each patient treated with SIJI received an explanation of the technique and informed written consent was obtained; subsequently, each patient was invited to lay prone on a medical bed while a musculoskeletal sonographer individuated sacroiliac joints (SIJ) with a convex probe and demarcated the needle entry site with a dermographic pen. A sterile hood was put on the probe, the skin was accurately disinfected, then a 2,5 mL syringe was loaded with 40mg of triamcinolone acetonide and a spinal needle of 22 gauge was used to reach SIJ. Each SIJI involved crossing the posterior sacroiliac ligament and each injection was carried out following real time the needle trajectory. All of the US-SIJ patients received a bilateral SIJI. The statistical analysis exploited descriptive statistics to define baseline anthropometric variables, ANOVA test and Test U of Mann were used to compare the means between groups. The p<0,05 was considered significant. The present study was conducted in accordance to the Declaration of Helsinki and was approved by the local ethical committee.

Results: We enrolled 33 subjects: 12 received an US-SUI and 21 were treated with a standard therapy according the most up-to-date recommendations. Both groups were comparable for age and VAS pain at baseline. In US-SUI group after 24 h was documented a significant reduction of VAS pain that lasted up to 1 year displaying always a persistent significant lower value compared to baseline; in SIJIs group the higher VAS pain reduction from baseline was documented after 7 days (- 71 %); in the control group VAS pain reduction reached significance after 3 months from baseline and the higher VAS pain reduction was documented at end of study (-32 %). In the US-SUI group MS dropped significantly after two weeks from SIJI while in the controls after 3 months from baseline. At the end of the study the patients treated with US-SUI displayed a higher VAS pain (-50 % in SIJIs vs. -32 %, p<0,05) as well as MS reduction compared to controls (- 71 % in SIJIs vs. -42%, p<0,05). Any serious adverse event was recorded.

Conclusion: The US-SIJIs represent a safe and useful tool to control the symptoms of an active sacroiliitis and they should be performed concomitantly to the beginning of a bDMARD therapy to guarantee a rapid restoration of patients' quality of life.
Background: Radiographic assessment of the sacroiliac joints (SIJ) according to the modified New York (mNY) criteria is essential in the classification of ankylosing spondylitis, but low to moderate inter-reader agreement and limited improvement by calibration have been reported [1]. A web-based real-time iterative calibration (RETIC) module for scoring SIJ radiographs according to the mNY criteria has been developed by experienced readers to allow remote standardized calibration.

Objectives: To test the performance of this online RETIC calibration module in enhancing scoring proficiency with an expert reader as gold standard reference.

Methods: This RETIC module consisted of 50 cases with radiographs of the SIJ at one timepoint with an integrated scoring interface with real-time feedback to the reader’s grading compared to the expert readers’ grading. The mNY grade (0-4) was assessed for each joint. Reliability for fulfilling versus not fulfilling the mNY criteria was assessed in real-time by kappa data being provided every 10 cases, until proficiency targets (kappa > 0.5) were achieved. In this study, 19 readers from the EuroSpA Imaging project were randomized to one of two reader calibration strategies (groups A and B) that comprised of 3 calibration steps, each followed by a reading exercise (Exercises 1-3; 25 patients per exercise).

Calibration steps were as follows: Group A: 1. Review of original manuscripts describing the mNY method. 2. Review of PowerPoint summary of mNY method and video with grading examples PLUS completion of mNY RETIC module. 3. Re-review of PowerPoint summary and video. Group B; same 3-step strategy as group A except that the mNY RETIC module was completed at step 3, i.e. immediately before Exercise 3. The reliability of scoring was compared to an expert radiologist (RL) using kappa statistics for positivity of mNY criteria and intraclass correlation coefficients (ICCs) for the grades of the mNY criteria.

Results: The mean agreement for all readers on fulfillment of the mNY criteria with kappa was 0.69 in exercise 1, 0.72 in exercise 2 and 0.83 in exercise 3. Corresponding ICCs for mNY scoring 0-4 were 0.77, 0.77 and 0.82 in exercises 1, 2 and 3, respectively, see Table 1 and Figure 1. For Reader Group A, kappas for exercises 1-3 were 0.65, 0.76 and 0.83, respectively and ICCs 0.71, 0.82 and 0.81 (exercise 3). Interestingly, the main increase in agreement occurred between Exercises 1 and 2, i.e. after the RETIC module was performed. For Reader Group B, corresponding kappas were 0.71, 0.77 and 0.83 and ICCs 0.80, 0.72 and 0.80, for exercises 1-3, respectively. Similarly, agreements predominantly improved directly after the RETIC module was performed.

Conclusion: Agreement on scoring radiographs of the SIJ according to the mNY criteria was noticeably improved when using a systematic online calibration module and in general readers achieved very good agreement with experts implying that systematic calibration of readers before scoring of images can enhance scoring proficiency.

# Reading performed right after doing the RETIC module.*Grading per sacroiliac joint/ICC: Intra-class correlation coefficient (two-way, single measurement, absolute agreement), mNY+: Fulfilling radiographic part of Modified NY criteria; mNY: Not fulfilling radiographic part of Modified NY criteria.
Results: At the joint level, PET/CT activity (SUV) was significantly different when the joint was under US remission or not (OR 0.411, p<0.0001 with remission defined as “no synovitis grade ≥ 2 with no PDI”). ROC-curves identified SUV thresholds to define joint remission with a high predictive positive value (95.2%; confidence interval (CI): 93.8-96.4), but with low negative predictive value (28.9; CI: 7.1-62.8). When wrists, MCP and PIP were evaluated separately, AUC was higher for wrists. Predictive positive value was high for each sub-type (93.4, 94.2, 96.3% respectively). Negative predictive value was low for MCP and PIP (34.0 and 22.2%) but better for wrist (71.4%). At the patient level, SUVmax was significantly different when the patient was under US remission or not (p=0.0023 with remission defined as “no synovitis grade ≥ 2, no PDI, no tenosynovitis”). Cumulative SUV was also different (p=0.045) while there was no difference for the number of PET-positive joints. SUVmax threshold was determined with ROC-curves and demonstrated a high negative predictive value for determining US remission (92.9, CI: 66.1-99.2), while the positive predictive value was lower (67.4, CI: 52.0-80.5). For cumulative SUV threshold, negative and predictive value for determining US-defined remission were 73.1 and 73.5 respectively.

Conclusion: PET/CT is able to predict US-defined remission in RA patients. In addition to its well-known role in cancer evaluation and systemic inflammation work-up, PET/CT is also a promising tool in RA metrology. When considering US remission at the joint level, the predictive positive value is high, while the predictive negative value is better when predicting US remission at the patient level. Among PET/CT parameters, the maximum SUV (SUVmax) and the cumulative SUV exhibit the highest performances to predict US remission.

Objectives: To assess tenosynovitis in wrist MRI scans from patients suspected of developing rheumatoid arthritis (RA), visual scoring (RAMRIS) is usually applied. As this time-consuming and requires rigorous training, we propose a method for the wrist that is based on Deep Learning (DL) combined with post-processing. This method detects all structures (a process called ‘segmentation’), including all tendons, and measures inflammation around each tendon (group).

Methods: Post-contrast axial MR scans of the wrist of 1216 patients with early-onset synovitis from the early arthritis clinic (EAC) cohort were used. From 28 EAC patients, ground truth manual segmentations were obtained as atlases. This dataset contains 33 labels: 14 flexor/extensor tendon groups; 10 carpal, 5 metacarpal bones; 1 label for all main vessels; 2 labels for skin and remaining tissue; and 1 air label. We normalized each input image using the Z-score. For tissue segmentation of the wrist (see Figure 1a), our method utilizes a U-Net. For data augmentations we used intensity scaling (0.8-1.25) and added normally distributed noise ($\mu=0, \sigma=0.06$). We used softmax cross-entropy as a loss function, 1-fold cross-validation evaluation, we trained on all 28 atlases. For validation we compared the automated tenosynovitis score against the manual RAMRIS score. From 10 RAMRIS tenosynovitis scores defined by two clinicians, we computed the mean score (Tm). To define starting and end MRI slices for the scoring area we followed the RAMRIS definition. Starting from the slice where radius and ulna are closest to each other, ending with the hook of the hamate. The scoring areas were computed 3mm around tendons, using a Euclidean distance transform, while excluding bones and vessels. Subsequently we computed histograms of the image intensities in the blood vessels and used the 25th percentile point as threshold to define inflamed areas within the scoring area (see Figure 1b). The final tenosynovitis quantification ($Tq$) was defined as the ratio between the number of ‘inflamed pixels’ and the total scoring area.

[PET] POSITRON EMISSION COMPUTED TOMOGRAPHY ([18F] FDG PET/CT) IS ABLE TO PREDICT ULTRASOUND-DEFINED REMISSION IN RHEUMATOID ARTHRITIS

Keywords: Inflammatory arthritides.

C. Rinkin1, C. Florane1, C. Gérard1, L. Seidel1, C. Lamaye2, R. Hustinx2, M. Malaise1, C. Ribbens1, O. Malaise1.

Background: Assessing joint inflammation in rheumatoid arthritis (RA) is of high importance because associated with structural damage. In addition to clinical examination and ultrasound (US), joint inflammation can also be quantified by [18F] positron emission computed tomography ([18F] FDG PET/CT). Nowadays, PET/CT is widely used for cancer evaluation and systemic inflammation work-up and it can be used for opportunistic joint evaluation in RA patients. In addition, PET/CT allows a whole-body articular evaluation in one examination. We, and others, have previously demonstrated that PET/CT is significantly correlated with US parameters, but with a weak correlation coefficient.

Objectives: We investigated the ability of PET/CT to predict US-defined remission at the joint level and at the patient level.

Methods: 61 RA patients were included and underwent [18F] FDG PET/CT and US evaluations. For PET/CT, standardized uptake value (SUV) was determined on 22 joints (wrists, PIP and MCP of both hands). At the patient level, the maximum SUV (SUVmax), the number of PET positive joints (SUV>0) and the sum of all SUVs (cumulative SUV) were evaluated. US evaluation included grayscale and Power Doppler imaging, according to OMERACT.

Results: The ratio between the number of ‘inflamed pixels’ and the total scoring area.

Acknowledgements: None Declared.
Results: In this work, we presented an alternative automatic quantification of tenosynovitis on MRI of the wrist. The results provide sufficient quantitative measurements compared to RAMRIS visual scores. The quantitative measurement was computed for 1216 patients, with Pearson correlation coefficient $r = 0.87$ and $p < 0.001$ (see the scatter plot in Figure 1).

Conclusion: Our DL-method provides a way to automate the quantification of tenosynovitis with MRI. It is very fast (~10 sec per patient) as compared to manual visual scoring. We illustrate the cumulative measurement of all synovial areas, while computing per tendon is also feasible. The accomplished results provide a solid basis for automatic tenosynovitis quantification.

In this post-hoc analysis, 139 patients (90 women and 49 men) with low back pain of mechanical/ non-inflammatory origin (after exclusion of axSpA) were included. The MR images of the sacroiliac joints were scored by two trained readers separately for the presence of axSpA features: ankylosis, erosions, sclerosis, fat metaplasia and bone marrow edema. The scoring was performed for the three SIJ regions (ventral/middle/dorsal) differentiated for the sacral and iliac sides. Frequencies of lesion per joint region were compared between HLA-B27 positive and negative individuals using Chi-squared tests. Extent of lesions, expressed as sum scores were compared using T-tests. All analyses were carried out for the entire group and for men and women separately.

Results: A total of 90 women and 49 men were included in this post-hoc-analysis. HLA-B27 was positive in 33/90 women (36.7%), while this was the case in 23/49 men (46.9%) (further clinical data is given in Table 1). There was no difference in frequency of overall occurrence of erosion (22.9% vs. 16.1%; $p = 0.392$), sclerosis (48.2% vs. 48.2%; $p > 0.999$), fat metaplasia (12.0% vs. 7.1%; $p = 0.403$), bone marrow edema (28.9% vs. 32.1%; $p = 0.710$) and ankylosis (2.4% vs. 3.6%; $p > 0.999$) between HLA-B27 negative and positive individuals, respectively. A detailed graphical representation of spatial distribution of lesion within the joint is given in Figure 1.

Conclusion: In our cohort of pre-selected patients with chronic low back pain and after exclusion of axSpA, the HLA-B27 status did not determine extent or pattern of imaging lesions in either men or women. These results somewhat contradict previously published data on healthy volunteers. This indicates that further studies are needed especially in the investigation of the sex-specific influence of HLA-B27 status on imaging lesions.

Methods: In this post-hoc analysis, 139 patients (90 women and 49 men) with low back pain of mechanical/ non-inflammatory origin (after exclusion of axSpA) were included. The MR images of the sacroiliac joints were scored by two trained readers separately for the presence of axSpA features: ankylosis, erosions, sclerosis, fat metaplasia and bone marrow edema. The scoring was performed for the three SIJ regions (ventral/middle/dorsal) differentiated for the sacral and iliac sides. Frequencies of lesions per joint region were compared between HLA-B27 positive and negative individuals using Chi-squared tests. Extent of lesions, expressed as sum scores were compared using T-tests. All analyses were carried out for the entire group and for men and women separately.

Background: The knowledge of factors influencing the susceptibility to and extent of changes at the sacroiliac joints (SIJs) are of great importance in the understanding of pathophysiological processes in axial spondyloarthritis (axSpA)[1]. Recent studies showed that previous delivery and the HLA-B27 status have a special role in the expression of bone marrow edema at the SIJs in the general population. Furthermore, the influence of HLA-B27 differed in men and women[1 2].

Objectives: The aim of this study was to investigate the sex-specific influence of the HLA-B27 status on the SIJ lesions such as ankylosis, erosion, fat metaplasia and bone marrow edema and its distribution and extent in patients with low back pain of non-inflammatory origin.

Methods: In this post-hoc analysis, 139 patients (90 women and 49 men) with low back pain of mechanical/ non-inflammatory origin (after exclusion of axSpA) were included. The MR images of the sacroiliac joints were scored by two trained readers separately for the presence of axSpA features: ankylosis, erosions, sclerosis, fat metaplasia and bone marrow edema. Differential diagnosis of focal Immunoglobulin G4-related Sialadenitis and benign salivary masses: the value of contrast-enhanced ultrasound

Keywords: Diagnostic tests, Ultrasound

Y. Xin¹, S. Zhang¹, F. Liu¹, J. Zhu¹. ¹Peking University People's Hospital, Department of Ultrasound, Beijing, China

Background: Immunoglobulin G4 related disease (IgG4-RD) is a newly recognized immune-mediated fibroinflammatory disease characterized by involvement of multiple organs, among which salivary gland is one of the most commonly involved sites. Immunoglobulin G4-related Sialadenitis (IgG4-RS) presents itself as focal or diffuse lesions, of which focal lesions are difficult to differentiate from salivary gland masses, especially benign masses with a high clinical incidence. Differential diagnosis of both sets of disorders has significant clinical implications due to different treatment modalities.

Objectives: The aim of this study was to clarify the effectiveness of contrast-enhanced ultrasound (CEUS) in differential diagnosis of focal IgG4-RS and benign salivary masses.

Methods: We retrospectively included 13 patients with diagnosis of focal IgG4-RS and 32 patients with pathologically confirmed benign salivary masses (32 benign masses).

Conclusions: CEUS was remarkably effective in differentiating focal IgG4-RS and benign salivary masses, its discriminatory value was superior to conventional ultrasound. The diagnostic accuracy can be more improved by effectively combining clinical data and laboratory findings.

Background: Both active and chronic lesions can be seen on sacroiliac MRI. Objective: Aim was to compare the demographic and disease characteristics of patients with active and structural lesions on sacroiliac MRI in a bDMARD cohort of Spondyloarthropaths (SpA) patients.

Methods: 1073 patients were included in the analysis. The patients were divided into active (1755 patients with SpA (including Psoriatic arthritis [PsA] and Enteropathic arthritis [Enteropathic arthritis (EA)])) and structural lesions on MRI. Patients were divided into four groups according to the diagnosis and disease severity in patients with psoriasis (PsO) and PsA.

Results: Of 1230 patients with sacroiliac MRI, 548 (44.5%) had only active lesions, 418 (33.9%) had both active and structural lesions, and 264 (21.5%) had only structural lesions. The diagnoses of the patients were s-RA 833 (67.7%), peripheral s-RA 329 (26.3%), nr-SPA 321 (26.1%), enteropathic SPA 79 (6.4%). PsA 64 (5.2%). From ‘only active lesion’ to ‘only structural lesion’ on MRI, age was older, disease duration was longer, meeting mNY criteria and hip involvement was more common, HLA-B27 positivity was more common, syndesmophyte was more common, uveitis was more common, and metrological indices (BASMI and Schober’s test) was worse (Table 1).

Conclusion: Transition from active lesions to structural lesions in sacroiliac MRI may be time-related, and chronicity develops in approximately 5 years. As expected, when structural lesions develop on MRI, the rate of meeting the mNY criteria increases around 3 times. There is a relationship between uveitis and the development of structural damage. The relationship of metrological indices with structural damage should also be considered. However, the lack of central reading in MRI is a limitation in this assessment.

USEFULNESS OF LOW-DOSE CT IN PSORIASIS AND PSORIARTHRITIS PATIENTS WITH NON-SPECIFIC AXIAL SYMPTOMS

Keywords: Imaging, Psoriatic arthritis

1Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2Hacettepe University, Department of Dermatology and Venereology, Ankara, Turkey

Background: Low-dose CT (IdCT) has been shown advantageous over conventional radiography (CR) in showing spinal structural changes in Axial Spondyloarthritis (AxSpA)1. There is no data on the value of IdCT in psoriatic arthritis (PsA) patients.

Objectives: The aim of this study is to determine the contribution of spinal IdCT to the diagnosis and disease severity in patients with psoriasis (PsO) and PsA with non-specific axial symptoms.

Methods: 143 PsO patients referred from the Dermatology Outpatient Clinic in the last 9 months were evaluated; patients with any axial symptoms (116) were included. 47 of 116 patients (40.5%) had IdCT. Patients were evaluated with pelvic CT (n=84), thoracic CR (n=84), lumbar/cervical CR and whole spinal IdCT. Age, gender, PsO and PsA disease duration were recorded. Patients were divided into four groups according to CR findings; 1. Modified New York criteria (mNY) not met, 2. Only sacroiliitis (SI) according to mNY criteria, 3. SI and syndesmophyte (SIN) present, 4. Only SIN present.

Results: From ‘only active lesion’ to ‘only structural lesion’ on MRI, age was older, disease duration was longer, meeting mNY criteria and hip involvement was more common, HLA-B27 positivity was more common, syndesmophyte was more common, uveitis was more common, and metrological indices (BASMI and Schober’s test) was worse (Table 1). Multivariate analysis showed factors associated with the development of structural lesions from active lesions, disease duration with OR 1.09 (CI 95% 1.04-1.14), mNY positive syndesmophyte with OR 3.36 (95% CI 1.52-7.40) and uveitis with 3.80 (95% 1.23-11.8).

Conclusion: Transition from active lesions to structural lesions in sacroiliac MRI may be time-related, and chronicity develops in approximately 5 years. As expected, when structural lesions develop on MRI, the rate of meeting the mNY criteria increases around 3 times. There is a relationship between uveitis and the development of structural damage. The relationship of metrological indices with structural damage should also be considered. However, the lack of central reading in MRI is a limitation in this assessment.

REFERENCE:
1. Bridging SIN and Andersen lesion were detected in 1/12 (8.3%) and 2/12 (16.7%) of PsO patients versus 17/35 (48.6%) and 8/35 (22.9%) of PsA patients, respectively. In 15/22 (68%) of those with normal CR, 7/19 (77.7%) of those with only SI in CR, 5/5 (100%) of those with only SIN in CR, and 11/11 (100%) of those with only SIN in CR were found to have syndesmophytes on idCT. Accordingly, 38/47 (80.8%) patients had at least one syndesmophyte on idCT (Table 1).

Conclusion: When PsO and PsA patients with non-specific axial symptoms were evaluated with spinal idCT, new syndesmophytes were found in a significant proportion of patients (2/3 of patients with only PsO), additionally an increased distribution of syndesmophytes was observed. The thoracic vertebra is one of the most frequently involved area in psoriatic disease similar with SpA. Comparative studies with a healthy control group are needed to determine the potential role of idCT.

AUTOMATIC SCORING OF ULTRASOUND SYNOVIAL HYPERTROPHY IN RHEUMATOID ARTHRITIS THROUGH INTEGRATING MULTIPLE CONVOLUTIONAL NEURAL NETWORK MODELS

Keywords: Rheumatoid arthritis, Artificial intelligence, Ultrasound

C. C. Huang1, P. Huang2, K. J. Yeo1, C. J. Chang2, C. C. Huang3, S. H. Chang4, J. L. Lan5, D. Y. Chen6, C. H. Kao7.1 China Medical University Hospital, Rheumatology and Immunology Center, Taichung, Taiwan, Republic of China; 2China Medical University Hospital, Center of Augmented Intelligence in Healthcare, Taichung, Taiwan, Republic of China

Background: The OMERACT-EULAR Synovitis Scoring (OESS) system is worldwide used to evaluate arthritis severity on ultrasound (US) images. Because of inter-observer and intra-observer variability, deep learning (DL) has been applied in high-quality image interpretation and analysis. Previous studies mostly focused on Doppler US (DUS) classification by convolutional neural network (CNN), which could provide objective assessment. However, the reports of DL intervention in grey scale (GS) US image automatic measurements are limited.

Objectives: The aim of this study was to develop an integrated multiple CNN model in precise scoring GS US images from rheumatoid arthritis (RA) patients.

Methods: The standard US images from patients of RA were retrospectively selected by three 10-years US experienced rheumatologist together and were graded according to the OESS system. Six different joint data were taken, including proximal interphalangeal, metacarpophalangeal, wrist, elbow, knee and ankle joints. We conducted the DL model integrating three binary CNNs to predict four-class GS US scoring (Figure 1). The accuracy of the trained model was tested by an independent test data.

Results: Total 678 images from 447 patients of RA were used in this study. These images were divided into training (n=611) and testing (n=67) sets. The integrated multiple CNNs model could achieve a four-class accuracy of 77.6%. The individual accuracy of grades 0, 1, 2 and 3 were 68.4%, 77.3%, 73.3% and 100%, respectively (Table 1). Furthermore, we found that adding on anatomic site parameters or labeling areas of interest would establish a better average area under curve (AUC) with 92.6% and 89.0%.

Conclusion: Our study suggests the possibility of using the integrated multiple CNNs model in grading synovial hypertrophy of RA, which is critical in RA healthcare. Extern- val validation would be required to confirm the predictive ability of this model.

POS0026

OPTICAL SPECTRAL TRANSMISSION IN THE DIAGNOSIS OF HAND OSTEOARTHRITIS: CLINICAL ASSOCIATIONS AND EVALUATION OF A NEW DIAGNOSTIC ALGORITHM INCLUDING ALL FINGER JOINTS

Keywords: Osteoarthritis, Imaging

K. Triantafylia1,2, K. Altamimi3, S. Gauch4, A. Schwarting1.1 Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany; 2Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany

Background: Optical spectral transmission (OST) is a modern diagnostic technology able to quantify joint inflammation in a non-invasive, rapid and examiner-independent manner [1-3]. The vast majority of studies on OST have been performed in patients with rheumatoid arthritis (RA) [1-3]. No sufficient data on the diagnostic value of OST regarding other arthropathies have been published. However, our study group and others could show that concomitant to RA joint pathologies, such as primary or secondary (post-arthritic) osteoarthritis (OA) could have an influencing effect on OST results [1,4].

Objectives: Aim of this study was therefore to investigate the performance of OST in the diagnosis of OA and to evaluate its ability to identify activated OA changes.

Figure 2. 4G Color Fig(s):0 21:36 Art: 15_EUROAB-2023-PV14-15
Methods: Patients from two large Rheumatology departments with diagnosed finger and/or wrist OA and without any inflammatory joint disease, as well as healthy controls, were recruited in the context of this study. All study subjects were evaluated via clinical (counts of tender and swollen joints) and OST examinations. Moreover, OA-patients underwent laboratory (C-reactive protein, erythrocyte sedimentation rate) and X-ray examinations of both hands and the extent of osteoarthritic changes was evaluated by an established radiographic score [Kellgren-Lawrence (KL) score]. To evaluate OA activity, joint ultrasound (US) examinations [Grey-scale (GSUS), power Doppler (PDUS) scores] were performed in a subset of patients. Moreover, a new diagnostic algorithm including the distal interphalangeal joints (DIP) was examined next to the established algorithm concerning only wrists, MCP and PIP joints.

Results: 2,134 joints of OA patients (n=97; 80.4%; 68 years (58-76, IQR)) and 2,200 joints of healthy controls [n=100; 80%; 49 years (33.5-56, IQR)] were examined via OST. OA patients showed statistically significantly higher OST scores compared to control subjects [13.75 (11.19-16.51, IQR) vs. 10.19 (8.05-14.31, IQR); p<0.001] during the evaluation of the algorithm including wrist, MCP and PIP joints. This difference remained significant also after adjusting for age and sex (p=0.033). The novel diagnostic algorithm including additionally DIP joints (next to MCP, PIP and wrists) showed also a statistically significant difference between patients and controls (p<0.001, after adjustment p=0.021). Interestingly, receiver operating characteristics revealed an improved diagnostic performance when including DIP joints in the algorithm [Area under the curve (AUC) 0.718; 95%CI (0.645-0.792) (with DIP) vs AUC 0.698; 95%CI (0.625-0.771) (without DIP)]. OST did not correlate with GSUS/PDUS or KL-Score (all; p>0.05). However, it did correlate moderately-significantly with patient hand-size (without DIPs: rho=0.337; p<0.001; with DIPs: rho=0.383; p<0.001).

Conclusion: Hereby we could show that presence of OA can indeed influence OST values and that OA changes should be taken into account when interpreting OST results. Moreover, we found that inclusion of DIP joints can lead to an improvement of diagnostic performance of OST. To our knowledge, this is the largest study examining the diagnostic value of OST in OA and the first external exploration of this specific DIP-associated algorithm. Value of OST in the follow up examinations of OA patients should be investigated in studies with longitudinal design.

DEEP LEARNING-BASED ASSESSMENT OF SALIVARY GLAND ULTRASOUND IMAGES FOR SUPPORTING THE DIAGNOSIS OF PRIMARY SJÖGREN’S SYNDROME

Keywords: Artificial intelligence, Sjögren syndrome, Ultrasound

Y. Geng1,1,1, X. Zhang2,2,2, Z. Zhang1,1,2, Peeking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China; Peeking University First Hospital, Department of Radiology, Beijing, China

Background: Salivary gland ultrasound (SGUS) has proven to be a promising tool for diagnosing primary Sjögren’s syndrome (pSS). However, the widespread use of it as standardized diagnostic tools is limited by inter/intra operator variability.

COMBINED BRAIN/HEART MAGNETIC RESONANCE IMAGING REVEALS SUBCLINICAL BRAIN LESIONS IN PATIENTS WITH INFILTRATIVE ARTHRITIDIES AND CARDIAC SYMPTOMS

Keywords: Imaging, Inflammatory arthritis, Diagnostic tests

G. Markousis-Mavrogenis1, A. I. Venetsanopoulou2, A. Pieta3, I. Ntalas3, C. Nakas4, L. Pagounis3, D. Toliopoulos3, G. Mouka3, P. Voulgari2, S. G. Markousis-Mavrogenis1, A. I. Venetsanopoulou2, A. Pieta2, I. Ntalas3, Imaging center, Ioannina, Greece; *University Research Institute of Maternal and Child Health and Precision Medicine, Medical School, National and Kapodistrian University of Athens, Aghia Sophia Children’s Hospital, Athens, Greece; **Center for Adolescent Medicine and UNESCO Chair in Adolescent Health Care, Medical School, National and Kapodistrian University of Athens, Aghia Sophia Children's Hospital, Athens, Greece

Background: Inflammatory arthritides (IA) can affect diverse body tissues beyond joints, including the heart [1,2]. Particularly in chronic inflammatory states, circulating immune mediators can also induce central nervous system inflammation [3]. Nevertheless, little is currently known about the consequences of cardiac inflammation on the occurrence of brain lesions in these patients.

Objectives: We hypothesized that patients with IA and cardiac symptoms would show evidence of brain lesions, and that the presence of cardiac inflammation would be associated with the presence of brain lesions. We thus investigated patients with IA and compared them to a cohort of disease-controls using combined brain/heart magnetic resonance imaging (MRI).

Methods: Patients with IA and shortness of breath, chest pain and/or palpitations (n=25) were compared to age-matched disease-controls with non-autoimmune cardiovascular disease (CVD) (n=30) using a 1.5T MRI system. The presence of white matter hyperintensities (WMHs) was investigated in subcortical/deep periventricular white matter, the basal ganglia, pons, brainstem, and mesial temporal lobe. Cardiac function and inflammation were investigated using standard protocols. Patients with IA were diagnosed with rheumatoid arthritis [14 (66%)], ankylosing spondylitis [5 (20%)], juvenile rheumatoid arthritis [3 (12%)], mixed connective tissue disease [2 (8%)], or osteoarthritis [1 (4%)]. Disease-controls had various CVDs including coronary artery disease [5 (17%)], myocarditis [5 (17%)], hypertension [3 (10%)], Duchenne muscular dystrophy [3 (10%)], and others.

Results: Patients with IA and disease-controls respectively had a median (IQR) age of 45 (39, 51) vs. 53 (40, 57) years (p=0.269), and 16 (64%) vs. 7 (23%) were women (p=0.002). WMHs were detected in ≥1 brain area in 15 (60%) patients with IA and 15 (54%) disease-controls (p=0.620). The majority of participants had WMHs in subcortical [29 (93%)], periventricular [5 (17%),] or deep WM [11 (20%)]. Some also had cortical lesions [5 (9%)], while basal nuclear, brainstem and mesial temporal lesions were rare [1 (2%) for all]. Amongst subjects with WMHs, the median (IQR) number of brain lesions in patients with IA and disease-controls was 1 (2) for both groups (p=0.635). There were no significant differences in the distribution of brain lesions between groups. Amongst patients with IA, each 0.1-unit increase in cardiac T2-ratio was associated with an increased odds ratio of WMH occurrence [odds ratio (95%): 1.29 (1.05-1.59), p=0.016] and higher cardiac T2-ratio (per 0.1-unit change) and extracellular volume fraction (ECV) were associated with a higher WMH lesion burden in linear regression analysis [Beta (95% confidence interval): 0.08 (0.01-0.15), p=0.021 and 0.22 (0.03-0.41), p=0.027, respectively]. MRI-derived left/right-ventricular ejection fraction, early/late-gadolinium enhancement and T1/T2 mapping were not associated with the presence of WMHs.

Conclusion: In patients with IA and cardiac symptoms, 60% showed evidence of subclinical brain lesions, which was on average as prevalent as in age-matched disease-controls with non-autoimmune CVD. Higher myocardial T2-ratio, an MRI-derived surrogate of myocardial edema, was associated with the presence of WMHs, and higher T2-ratio as well as myocardial ECV values were predictive of higher WMH burden. Further research is required to determine the clinical relevance of these findings.

**Objectives:** The aim of this study was to evaluate the utility of deep learning-based SGUS image assessment in the diagnosis of pSS.

**Methods:** Between Sep 2021 and Oct 2022, 1133 SGUS images of 137 patients from one center were included in this retrospective study. Among them, 61 patients with 480 images were diagnosed as pSS and 76 patients with 653 images were non-SS. All the SGUS image data were randomly divided into training dataset (50%), validation dataset (20%) and testing dataset (30%). The SGUS automatic classification model was developed by using a deep residual convolutional network architecture (RESNET). The predictive performance was validated by sensitivity, specificity and area under receiver operating characteristic curve (ROC).

**Results:** When applying deep learning-based SGUS image assessment, it showed better performance than operator based SGUS score system by improving the specificity (86.9% vs. 80.1%), while similar sensitivity (59.9% vs. 61.4%). The area under the ROC were comparable between them (0.800 vs 0.775).

Conclusion: When using deep learning-based SGUS, the proposed automatic and promising tool compared to expert-based scoring of SGUS in the diagnosis of pSS. This may support SGUS as an effective and prospective diagnostic tool to supplement current diagnostic methods.

**VALUE OF LUNG ULTRASOUND FOR THE DETECTION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**Keywords:** Rheumatoid arthritis, Lungs, Ultrasound

R. Tanten, J. Marin2, J. Zacariaz2, J. Martiano3, M. Fullana4, R. N. Alvarado5, J. RosＡ. Hospital Italiano de Buenos Aires, Sección Reumatología, Buenos Aires, Argentina; Hospital Italiano de Buenos Aires, Sección Reumatología, Buenos Aires, Argentina; Hospital Italiano de Buenos Aires, Sección Neumonología, Buenos Aires, Argentina; Hospital Italiano de Buenos Aires, Sección Neumonología, Buenos Aires, Argentina; Hospital Italiano de Buenos Aires, Sección Reumatología, Buenos Aires, Argentina

**Background:** Interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA) associated with increased morbidity and mortality. High-resolution computed tomography (HRCT) is the gold standard for ILD diagnosis, but it has high cost and risk of ionizing radiation. Lung Ultrasound (LUS) is a non-invasive, low-cost, non-ionizing and easily performed diagnostic tool. The aim of this study was to evaluate the utility of LUS in ILD in patients with RA, using chest HRCT as the gold standard.

**Methods:** A cross-sectional study was performed at the Hospital Italiano de Buenos Aires, Argentina. Consecutive patients with RA (ACR/EULAR-2010 criteria), who had a chest HRCT performed at least 12 months previous to inclusion, were included. Demographic, clinical, laboratory and therapeutic data were recorded. Each patient underwent a LUS with a simplified examination (14 bilateral lung intercostal spaces -LIS-) and assessment of B-lines (BL) and pleural irregularities (PI). Additionally, a 6MWT was performed on each patient. For the diagnosis of ILD, HRCT was the gold-standard, taking as a threshold an extension of interstitial involvement ≥10%, scored by an expert lung specialist.

**Objectives:** To establish the diagnostic value of LUS in ILD in patients with RA, using chest HRCT as the gold standard.

**Results:** A total of 104 RA patients were included, 21.8% with ILD, 82.7% (95% CI 74.0-89.4) were women, with a median age at diagnosis of RA of 57.5 years (IQR 47.3-67.2) and a median disease duration of 8.7 years (IQR 3.3-15.8). 96.2% of patients (95% CI 90.5-98.9) were seropositive for rheumatoid factor (RF) and/or anti-citrullinated protein antibodies (ACPA), and median DAS28 (ESR) was 3.19 (IQR 2.8-6.4). Menthoxate had been used at some point of the disease in 94.2% patients (CI 87.3-97.8), and 46.2% (95% CI 36.5-56.2) were under bDMARDs or tsDMARD treatment at inclusion. Patients with ILD were older at the time of RA diagnosis (64 vs 54 years, p <0.002) and had higher erythrocyte sedimentation rate (ERS) and C-reactive protein (CRP) (48 vs 29 mm/h and 5.9 vs 3.9 g/l, p <0.002) than patients without ILD. In LUS, patients with ILD had more BL (median 26 vs. 1, p <0.001) (Figure 1) and PI (median 12 vs. 4, p <0.001) than patients without ILD. The diagnostic accuracy in ROC curves was: AUC 0.88 - 95% CI 0.78-0.93 for BL and AUC 0.82 - 95% CI 0.74-0.89 for PI (Figure 3 and 4). The best cut-off point for ILD detection was 8 BL and 7 PI. The performance of LUS was more sensitive than 6 MWT (Table 1).

**Conclusion:** The presence of BL and/or PI in the LUS showed an adequate diagnostic performance for ILD, with a good negative prognostic value.

**SUBCLINICAL SYNOVITIS OF THE KNEE REMAINED IN ONE-THIRD OF CASES IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY: MUSCULOSKELETAL ULTRASONOGRAPHY STUDY**

**Keywords:** Rheumatoid arthritis, Ultrasound

Y. Miyoshi1, E. Takamatsu1, R. Takada2, Y. Nagase2, 1Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Tokyo, Japan; 2Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Surgery, Tokyo, Japan

**Background:** There is no report investigating the prevalence, sites, and risk factors of knee synovitis in patients with rheumatoid arthritis (RA) after total knee arthroplasty (TKA).

**Objectives:** This study aimed to clarify the prevalence, anatomical distribution, and risk factors of knee synovitis in RA patients after TKA.

**Methods:** This study was a retrospective cross-sectional study. Subjects were patients who met the 2010 ACR/EULAR RA classification criteria and underwent TKA at Tokyo Metropolitan Tama General Medical Center. Knee joints on surgically treated sides were assessed by musculoskeletal ultrasound (MSUS) from April 1, 2020, to March 31, 2022. Knee US-synovitis was defined as the presence of PD ≥2 or higher at joint synovium (suprapatellar bursa, medial/lateral parapatellar joint recess, medial/lateral fibotemoral joint space).

**Results:** Forty-five patients with RA after TKA underwent MSUS, with a total of 71 knee joints (38 right, 33 left). Patient background: age (years) 74±10.0, female(%): 84%, disease duration (years) 20.6±10.4, TKA postoperative period (years) 5.7±4.0, ACPA positivity 77%, RF positivity 79%, DAS28(ESR) 3.1±1.03, mHAQ 0.8±0.8, PSL users 44%, MTX users 64%, csDMARDs users 87%, BDMARDs users 44%, tsDMARDs users 0%, Knee injury and Osteoarthritis Outcome Score-pain (KOOS-P) 82.5±17.2. The number of joints with GS 2 or higher...
was more prevalent than that with PD 2 or higher (Figure 1). The number of post-TKA knee joints with PD 2 or higher was 18 (25.3%) out of 71. The knee joints assessed within one year from TKA were more likely to have joint synovitis detected by MSUS than those over one year (5 joints (62.5%) vs 13 (20.8%). Fifteen (33.3%) patients had US-synovitis at post-TKA knee joints. There was no difference in disease activity scores (DAS28-CRP, DAS28-ESR, SDAI, CDAI), patient pain Visual Analogue Scale, or KOOS-P in patients with knee US-synovi-
tis (n=15) compared with those without knee US-synovitis (n=30). There was no significant correlation between PD grades and KOOS-P (p=0.73).

Conclusion: Subclinical US-synovitis of the knee still remained in one-third of cases in patients with RA after TKA. US-synovitis at post-TKA knee joints did not correlate with knee pain scores. The knee prosthesis would have a protective effect on synovitis-induced pain at post-TKA knee joints in RA.

USEFULNESS OF MUSCULOSKELETAL ULTRASOUND IN CLINICAL DECISION-MAKING IN RHEUMATOLOGY CLINICAL PRACTICE

Keywords: Ultrasound, Descriptive studies, Work-related issues

M. Serrano Warleta1, A. Palomeque Vargas1, R. Manzo1, C. Guillén-Astete1.

1Ramon y Cajal University Hospital, Rheumatology, Madrid, Spain

Background: Ultrasound (US) has proven to be a useful technique in the routine clinical practice of rheumatologists. Due to its low cost, accessibility, and the large amount of information it provides us, more and more ultrasound studies tend to be carried out. However, we wonder about the real clinical-ultrasound correlation and whether, after a given result, the clinician made decisions based on said result. Objectives: To describe the reason for request of the sonographic studies in our department and the effect of its result in the decision-making in the clinical practice.

Methods: Cross-sectional, observational analytical study. We enrolled all the patients that were cited in the ultrasonography agenda from march to august 2022. Variables for identification of request-exploration-review management times, motivation for the request, topography of the exploration performed, corre-
lation with clinical suspicion and effect on decision-making were collected. Data extraction was performed by four different observers. Quality control was per-
formed by a fifth observer.

Results: Records of 462 medical actions were included in the US agenda over 6 months. Including double requests (211 were bilateral scans), the results of 673 US scans performed were reviewed. Of the requests made, 118 (25.5%) were from patients with known diagnoses of inflammatory diseases. The attached Table 1 summarizes the reasons for the request and topography of the exploration of the studies carried out. The waiting time and standard deviation (SD) until the test was performed from its request was 85.4 SD 54.3 days (0.574) and until the reassesse-
ment of clinical suspicion was confirmed in 277 studies (59.2%), it was not demon-
strated in 161 (34.4%) and did not apply in the rest. The frequency of bilateral studies whose result could have been obtained with a unilateral exploration was 37/211 (17%). In 72 studies we could not determine to what extent US examina-
tion changed clinical decision (review query not available or not applicable). In 132 studies (33.8%) the clinician intensified the treatment, in 40 (10.2%) the clinician de-intensified the treatment, and in 63 (16.1%) the clinician indicated the discharge of the patient. Among those cases in which US modified the clinical decision, the time between test-requesting and decision-making was 120.1 SD 64.3 days, while in cases in which there was no effect on the clinical decision it was 160.9 SD 61.3. (p=0.0031).

Conclusion: Our study is limited to identifying bivariate associations between deci-
dion making and the result of a complementary test. The authors recognize that clinical decisions are made considering all available information, including those from specific complementary test. US proves to be a useful test in clinical decision-mak-
ing and presumably more so the less time elapses between its request and its interpretation. In addition, performing bilateral US scans seems justified as less than a fifth of the requests would have given the same result with a unilateral scan.

ULTRASOUND-DEFINED GRADE I SYNOVITIS IN PATIENTS WITH INFLAMMATORY-SUSPECTED ARTHRALGIA AND ITS ROLE IN DIAGNOSIS A YEAR LATER

Keywords: Ultrasound, Inflammatory arthritides, Diagnostic tests

A. M. Ruiz Beierano1, A. Corral Bote1, J. Arroyo Palomo1, B. A. Blanco Cáceres1.

1Hospital Universitario Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Musculoskeletal ultrasound is frequently used in several rheu-
matology units to detect subclinical inflammation in patients with joint symptoms suspected for progression to inflammatory arthritis.

Objectives: The main goal is to investigate the correlation between synovitis grade I (EULAR-OMERACT combined score) and the diagnosis of established inflammatory arthropathy that is carried out after a follow-up period of one year since the first ultrasound findings. The assessment is done in an ultrasound-spe-
cialized unit of a Rheumatology Department.

Methods: We conducted a descriptive, retrospective and unincentric study where 135 patients were selected from the ultrasound-specialized unit of our rheumatology department from July 2018 to December 2021. Patients that pre-
sented synovitis grade 0,2 and/or 3 on combined score were excluded. Collected baseline data included age, sex, immunological profile, acute phase reactants and physical examination previous to the ultrasound findings, as well as the
diagnosis made by the rheumatologist a year after said findings. To achieve that, the patients are divided into two groups: those who were diagnosed with inflammatory arthropathy and those who were not. In addition, non-parametric statistical tests for comparing means were used.

**Results:** The mean age was 55 years and 75% of the patients were females. At the beginning, clinical examination revealed a median of one tender joint and none swollen. Previous diagnosis of psoriasis was present in 18 (13.3%) patients while inflammatory bowel disease was present in 6 patients (4.4%). Of the 135 patients, after a year follow-up, 48 (34.1%) received the diagnosis of inflammatory arthropathy after a follow-up of one year: 15 (32.6%) psoriatic arthritis, 8 (17.4%) rheumatoid arthritis, 8 (17.4%) undifferentiated arthritis, 4 (8.7%) spondyloarthritides, 4 (8.7%) calcium pyrophosphate dehydrate crystal-related joint disease, 3 (6.5%) reactive arthritis, 2 (4.3%) systemic sclerosis, 1 (2.2%) Sjögren syndrome and 1 (2.2%) polyamyloidic rheumatica. Non-inflammatory arthropathies were also found 89 (65.9%), of which 64 (71.9%) were osteoarthritis, 20 (22.5%) Carpal tunnel syndrome and 5 (5.6%) had other soft tissue disease.

In the group of patients who did not developed an autoimmune arthropathy, 3 were Rheumatoid factor-positive and 10 were AAN-positive, none of them were aCCP-positive; The HLA B27 and Cw6 test resulted in 5 patients testing positive in HLA-B27 and none in Cw6. Among the group of patients that developed an inflammatory arthropathy the median of joints with ultrasound involvement was 2. Grade I power Doppler signal was detected in one case. 7 (15.2%) patients were RF- positive, and 6 (13%) aCCP-positive. AANs were positive in 13 cases (28.3%). There were no significant differences for clinical variables and acute phase reactants (Age, sex, SJC, TJC, RCR, ESP) between both groups. Comparing the immunological profile through a Fisher’s exact test, we obtained a statistically significant association for RF (p=0.033), aCCP (p=0.001) and AAN (p=0.014) in the group who finally received the diagnosis of inflammatory arthropathy. No other significant differences were found (Total joints GSUS, total joints PDUS, HLA B27 and HLA Cw6).

**Conclusion:** Despite the limitations and possible statistical bias that might appear in a retrospective study, there are a remarkable number of patients with ultrasound-defined grade I synovitis who develop inflammatory arthropathy a year later. Rheumatoid factor, aCCP and AAN positivity were the only factors statistically associated with progression.

**Background:** During pregnancy, exchanges between mother and fetus are provided by the placenta. Defects in the early stages of placentation prevent the creation of a high-flow, low-resistance circle resulting in an impaired maternal-fetal exchange. The development of aberrant microcirculation leads to placental abnormalities, detectable by placental histologic examination [1].

**Objectives:** To assess whether nailfold videocapillaroscopy (NVC), in combination with umbilical artery doppler ultrasound (UA-dU), can detect microvascular status during pregnancy [2]; and to evaluate if NVC follow-up during pregnancy might operate as a red flag biomarker of placental microcirculation abnormalities.

**Methods:** We conducted a longitudinal observational exploratory study on 54 healthy pregnant women (age range 26-46 y) within the 16th gestational week, excluding those with cardiovascular comorbidities. We performed clinical, UA-dU and NVC evaluation with an optical probe (200x magnification) at each trimester of pregnancy and post-partum [3]. We performed an after-birth placenta histology (abPH) in a subgroup of 20 women (among the 54 women) who developed complications during pregnancy (e.g., gestational hypertension) evaluated through optical microscopic technique, according to Amsterdam criteria [4].

**Results:** We noticed over time, in the whole cohort, a statistically significant increase in neo-angiogenesis (p<0.05), considering the absolute count of microvessel ramifications (aberrant shapes) (Figure 1a). Conversely, we did not observe any statistically significant variation in capillary density (n/linear mm), microhaemorrhages or dilated capillaries over time. Besides, a statistically significant difference in the absolute number of capillaries in the first trimester between subjects with and without areas of placental dysmaturation (aberrant placental microcirculation) was detected at abPH (7.0/mm ± 0.82 vs 8.2/mm ± 0.62; p=0.030), (Figure 1b). A receiver operating characteristic curve was drawn for calculating the Area Under the Curve (AUC: 0.87; 95%CI: 0.66–1.00), identifying the optimal discriminatory cut-off value for prediction of placental dysmaturation areas ≥(5.0/mm capillaries; sensitivity: 88.9%; specificity: 75.0%). Of note, a similar difference was confirmed at the third trimester, although not reaching statistical significance (p=0.06). Not any significant association was found between UA-dU and any of the assessed NVC parameters.

**Conclusion:** This study confirms, in a large cohort of pregnant women, the NVC detection of increased neoangiogenesis over time, even during post-partum. In addition, this is the first report suggesting the possible role of NVC (capillary density) for the early detection of aberrant placental microcirculation noticeable at abPH. A study in pregnant patients affected by autoimmune connective tissue diseases has already started, using those findings as reference parameters.

PREVALENCE AND TRENDS OF PULMONARY HYPERTENSION IN AUTOIMMUNE DISEASES

Keywords: Lungs, Comorbidities, Epidemiology

P. Khandwala1, D. Desai2, M. Sen1, 1Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America; 2Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America

Background: Pulmonary hypertension (PHTN) is a known complication of connective tissue diseases such as Systemic lupus erythematosus (SLE), Scleroderma (ScI), and Mixed connective tissue disease (MCTD). [1] The underlying mechanism for development of PHTN is remodeling and vasoconstriction of pulmonary arteries and arterioles. [2] There have been cases of severe PHTN in SLE patients that have shown improvement with immunosuppressive therapy, hence accentuating the role of inflammation in pathogenesis. [3] The Prevalence of PHTN is not well studied, and there are no large cohort studies available. This study was undertaken to capture the trend in the prevalence of PHTN in the aforementioned diseases.

Objectives: To determine the prevalence of PHTN in SLE, ScI, and MCTD, analyze the trend over a 15-year period as well as identify racial predisposition, length of stay (LOS), and cost of hospitalization in these patients.

Methods: We used the Nationwide Inpatient Sample database (years 2003-2018) and extracted patients with PHTN using validated International Classification of Disease (ICD) codes. Data from 2015 was excluded from the study considering the transition of the coding system from version 9 to 10. We identified cases having the diagnosis of SLE, ScI, and MCTD. Prevalence, as well as demographics, cost of hospitalization, and length of stay (LOS), were analyzed and charted. Data were analyzed using statistical analysis system 9.4 software.

Results: Over the period of 15 years, we identified 2,155,750 cases of PHTN. As seen in the graph, patients with SLE had the highest prevalence of PHTN. The prevalence rate of SLE in PHTN cases in 2003 was 0.92% which significantly increased to 1.05% in 2018, with a peak of 1.15% seen in 2014 (p<0.0001). The prevalence rate of ScI in PHTN decreased from 1.07% in 2003 to 0.80% in 2018 (p<0.0001). It was seen that the prevalence rate of MCTD in cases with PHTN significantly increased from 0.06% in 2003 to 0.23% in 2018 (p<0.0001). It was observed that the average age of PHTN cases was significantly younger in SLE (55.60 vs 70.80 years, p<0.0001), ScI (62.94 vs 70.72 years, p<0.0001), and MCTD (58.49 vs 70.66 years, p<0.0001). On examining the racial distribution, African Americans, Hispanics, and Native Americans were more likely to have underlying SLE, ScI, and MCTD, respectively. PHTN was more prevalent in females in all 3 diseases. The average cost of hospitalization was significantly higher in PHTN cases with MCTD ($76,696.7 vs $65,643.3, p<0.0001) and ScI ($69,106.5 vs $65,620.6, p<0.0001), while it was not significantly lower in PHTN cases with ScI ($65,272.9 vs $65,659.9, p=0.65). Average LOS was significantly longer in PHTN with MCTD (7.02 vs 6.64 days, p=0.0119). Though not significant, average LOS was longer in PHTN with ScI (6.73 vs 6.64 days, p=0.0812) and shorter in PHTN with ScI (6.62 vs 6.64 days, p=0.7917).

Conclusion: Improved survival, seen secondary to increased awareness, better diagnostic testing, multidisciplinary team approach, and newer treatment modalities has led to an increase in the prevalence of patients living with PHTN. Interestingly, our study shows that the prevalence of PHTN in SLE and MCTD is increasing while decreasing for ScI. Racial predisposition becomes evident, which demands a higher index of suspicion for the early diagnosis of PHTN in the respective races. There is a higher socioeconomic burden for patients with PHTN and autoimmune disease, as reflected by the increased LOS and cost of hospitalization.

THE COURSE OF CYTOKINE AND CHEMOKINE GENE EXPRESSION IN CLINICALLY SUSPECT ARTHRAGLIA PATIENTS DURING PROGRESSION TO INFLAMMATORY ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines

J. Heutz1, C. Rogier1, E. Niemantsverdriet2, S. Van den Eeden3, P. De Jong1, E. Lubberts1, A. Geluk1, A. Van der Helm – van Mil1,2, 1Erasmus MC, Rheumatology. Rotterdam, Netherlands; 2Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 3Leiden University Medical Center (LUMC), Infectious Diseases, Leiden, Netherlands

Background: Autoantibody-responses rise years before onset of inflammatory arthritis (IA) and are stable during transitioning from clinically suspect arthralgia (CSA) to IA. Cytokine and chemokine levels also rise years before IA-onset. However, the course in the at-risk stage of CSA during progression to disease or non-progression is unknown.

Objectives: To increase the understanding of processes mediating disease development, we studied the course of cytokine, chemokine and related receptors gene expression in CSA-patients during progression to IA, and in CSA-patients who ultimately did not develop IA.

Methods: Whole-blood RNA-expression of 37 inflammatory cytokines/chemokines/receptors was determined by dual-colour reverse-transcription multiplex ligation-dependent probe amplification, in paired samples of CSA-patients at CSA-onset and either at IA-development or after 24-months without IA-development. ACPA-positive and ACPA-negative CSA-patients developing IA were compared at CSA-onset and during progression to IA. GEE-models tested changes over time. A false discovery rate approach was applied.

Results: None of the cytokines/chemokine genes significantly changed in expression between CSA-onset and IA-development (Figure 1A). In CSA-patients without IA-development, G-CSF expression decreased (p=0.001), whereas CCR6 and TNIP expression increased (p<0.001 and p=0.002, respectively) over a 2-year period (Figure 1B). Expression levels in ACPA-positive and ACPA-negative CSA-patients who developed IA were similar.

Figure 1. (A) Modelled course of gene expression of 37 cytokines/chemokines/receptors in CSA-patients that progressed to IA. Cytokines, chemokines and related receptors were measured as baseline and at time of IA-development and for reasons of clarity presented in two plots. No statistically significant changes were observed during follow-up. (B) Modelled course of gene expression of CCR6, G-CSF and TNIP1 in CSA-patients that did not progress to IA. Cytokines, chemokines and related receptors were measured in paired samples from each patient with 2-year intervals. For comparison, the course of patients that progressed to IA was included, here the 2nd samples was collected at IA-development. CSA, clinically suspect arthralgia; IA, inflammatory arthritis.

Conclusion: The higher the Boruta importance score, the stronger the impact the particular input variable has on the outcome variable.

Results: The cohort comprised 1,329,698 new opioid users (801,533 women [60.3%]; 599,162 White patients [88.2%]), with a mean age of 60 years [SD 17]. The proportion patients with different RMDs in order of frequency were OA: 1,246,574 (93.7%); RA, 50,000 (3.8%); fibromyalgia [47,708, 3.6%], PsA [11,181 (0.8%)]. SLE [6,757 (0.5%)] and AS [6,560 (0.5%). Of our study population, 4,016 individuals (0.3%) experienced a hospitalization for opioid-related harms within our follow-up period of five years after first prescription date. Logistic regression and random forest models showed consistent results when ranking the most important variables associated to opioid-related hospital admissions. The main risk factor identified consistently across both methods was history of alcohol abuse, with an odds ratio (OR) of 10.7, 95% confidence interval (95% CI): 8.1–14.2 and Boruta Importance (Imp) of 93.6. Other main risk factors included history of attempted suicide and self-harm (OR 7.5, 95% CI: 5.6–9.9, Imp: 80.3), major depression (OR 2.0, 95% CI: 1.7–2.3, Imp: 39.7) and lower socioeconomic status (OR: 10.4, 95% CI: 4.6–23.4, Imp: 34.0).

Conclusion: Patients with a documented history of alcohol excess, severe psychological problems and those most socioeconomically deprived were found to have a higher risk of opioid-related hospitalisations. Medical providers should be made aware of psychosocial factors associated with opioid hospital admissions when prescribing opioids to patients with RMDs. By determining patient subgroups most vulnerable to opioid-related harms and further analysing patient risk factors, we hope to contribute to the development of targeted interventions for safer future clinical care.

PROLONGED PHYSICAL STRAIN AT WORK CONFRONS RISK FOR DEVELOPMENT OF RHEUMATOID ARTHRITIS IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA: CUES FOR MECHANICAL FACTORS AS FINAL PATHOPHYSIOLOGICAL HIT

Keywords: Rheumatoid arthritis, Epidemiology, Work-related issues

B. Van Dijk1, A. M. P. Boeren1,2, S. Khidir1, N. Den Hollander1, A. Van der Helm – van Middendorp1,2, Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands;3Erasmus Medical Centre (EMC), Rheumatology, Rotterdam, Netherlands

Background: Some case-control studies have identified physical workload as a risk-factor for rheumatoid arthritis (RA).

Objectives: To better understand its influence on the pathophysiological trajectory of RA-development, we studied the relation of work-related physical strain with MRI-detected joint-inflammation in clinically suspect arthralgia (CSA) and the general population, and with progression from CSA to clinical arthritis.

Methods: 501 consecutively presenting CSA-patients and 155 symptom-free persons filled out questionnaires on their occupation. Physical strain was determined using the International Standard Classification of Occupations (ISCO) per subject-reported occupation. Contrast-enhanced hand-MRIs were evaluated for synovitis/tenosynovitis/osteitis (summed as joint-inflammation) using the RAMRIS-method. CSA-patients were followed on clinical arthritis development (median follow-up 25 months). Analyses included interaction with age as proxy for prolonged physical strain.

Results: In CSA-patients, the degree of physical strain was associated with the severity of subclinical joint-inflammation, independent of BMI/smoking/education-level: there was a positive interaction between age and physical strain; p=0.007. Plotting the age-dependent effects showed a positive relation in CSA-patients aged ≥50 years (Figure 1A), suggesting the effect relates to prolonged physical strain. Especially tenosynovitis was increased in relation to higher physical strain in symptom-free persons not associated with MRI-detected joint-inflammation. Older (≥ 50 years) CSA-patients with higher physical strain developed clinical arthritis more often (Figure 1B; HR 1.17 [95%CI 1.00–1.35] per 10 percentage-points physical strain increase; p=0.043). This was partially mediated by subclinical joint-inflammation. Moreover, physical strain partially mediated the known association between low educational attainment and clinical arthritis development.

Conclusion: Prolonged work-related physical strain increases the risk of developing RA in CSA-patients, which is partially mediated by an effect on increased subclinical joint-inflammation. This points to mechanical factors as a final hit in the pathophysiology of RA-development.

Figure 1. A. Curves depict the total MRI-inflammation score predicted by multi-variable negative binomial regression, assuming 'average patient' with average BMI (28.7 kg/m2), who are non-smokers and who have intermediate or high educational attainment.

HR 1.17 [95%CI 1.00–1.35; p=0.043] per 10 percentage-points increase in physical strain at work. Textiles were used in the figures for illustrative purposes: low (<33%), middle (33–66%) and high (>66%) work-related physical strain.

prognosis in CTD-ILD patients [3]. Approximately one third of the patients with ILD meet criteria for a CTD [4].

Objectives: A) To determine the prevalence of PPFE in a cohort of Spanish patients with CTD-ILD, and B) to compare the characteristics between CTD-ILD patients with and without PPFE.

Methods: A total of 99 patients with CTD-ILD (31 rheumatoid arthritis (RA), 31 systemic sclerosis (SSc), 21 idiopathic inflammatory myositis (IIM), 6 primary Sjögren’s syndrome (SS), 4 systemic lupus erythematosus (SLE) and 6 with other CTDs) from the Hospital Universitario Marqués de Valdecilla (Santander, Spain) were included in this study. The presence of PPFE was confirmed by experienced radiologists evaluating chest high-resolution computed tomography images from all patients. In addition, demographic, clinical and radiological characteristics were collected.

Results: The presence of PPFE was found in 9 (9.1%) of the 99 CTD-ILD patients, whereas the remaining 90.9% had no signs of PPFE. In particular, it was confirmed in 4 patients with RA (12.9%), 2 with SSc (6.5%), 1 with IIM (4.8%), 1 with primary SS (16.7%) and 1 with SLE (25.0%) (Figure 1). The prevalence of bronchial dilation was statistically higher in CTD-ILD patients with PPFE compared to those without PPFE (44.4% versus 6.4%, respectively, p=0.006).

Background: Co-existing psoriatic arthritis (PsA) in patients with systemic sclerosis (SSc) has been reported. However, it is unclear whether SSc contributes as a risk factor for development of PsA.

Objectives: We aimed to assess whether SSc is associated with the risk of incident PsA.

Methods: From the Korean National Health Insurance Service database, 4,933 patients with SSc and 24,665 age- and sex-matched controls were selected. Hazard ratios (HRs) and 95% confidence intervals (CIs) for incident PsA were estimated using multivariable Cox proportional hazard models adjusted for known risk factors of PsA. Further, we selected individuals whose health check-up data were available (2,355 patients with SSc and 11,775 age- and sex-matched controls) in this population, we further adjusted for additional risk factors of PsA using the health check-up data.

Results: In the analysis of 4,933 patients with SSc and 24,665 age- and sex-matched controls, incidence rates of PsA in patients with SSc and controls were 10.56 and 3.20 per 1,000 person-years, respectively. After adjusting for risk factors of PsA, patients with SSc had a significantly higher risk of incident PsA (adjusted HR: 3.055 [95% CI: 2.597, 3.594]). Moreover, in the analysis of individuals who had health check-up data, additional risk factors of PsA were further adjusted; the result also showed that patients with SSc have a significantly higher risk of incident PsA (adjusted HR: 2.820 [95% CI: 2.207, 3.603]).

Conclusion: In this large cohort study, SSc was associated with a 3-fold higher risk of incident PsA than controls, independent of known risk factors of PsA. This observation advances our knowledge by showing that a risk relationship exists between SSc and PsA beyond a simple co-existence between the two conditions.

A GENETIC STUDY ABOUT POTENTIAL CAUSAL RELATIONSHIP BETWEEN SEDENTARY ACTIVITY AND PSORIASIS

Keywords: Genetics/epigenetics, Psoriatic arthritis

J. Y. Chen1,2, Q. Feng1,2, Q. Zhen1,2, Y. Feng1,2, Q. Yu3, P. F. He3,4, X. Li3,4, S. Zhang1,2,4, Shaxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China; 2Shaxi Medical University, Key Laboratory of Cellular Physiology at Shaxi Medical University, Ministry of Education, Taiyuan, China; 3Shaxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; 4The Second Hospital of Shaxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Psoriasis is a common, chronic, immune-mediated skin disorder, which is characterized by clearly demarcated areas of erythematous plaques with overlying silvery scales appearing on the skin [1]. Previous studies have shown that plenty of psoriasis patients are engaged in less physical activity (PA), however, the genetic causal association between PA and psoriasis is of scarce evidence [2].

Objectives: In this study, we aimed to evaluate the causal association between PA and psoriasis.

Methods: We used genome-wide association study (GWAS) data to conduct a Two-Sample Mendelian randomization (MR). MR utilizes single nucleotide polymorphisms (SNPs) as instrumental variables (IVs) to examine the causality of an observed association between exposure and outcome [3]. SNPs that were included in the analysis were those which had a correlation (r2 < 0.001) and without linkage disequilibrium and strongly related to PA (p < 1e-08, F > 10). All data were selected as IVs. PA was divided into two parts including sedentary and physically active activities. Physically active behaviors include accelerometer-based physical activity, vigorous physical activity, moderate to vigorous physical activity, moderate physical activity 10+ minutes, and vigorous physical activity 10+ minutes. GWAS summary data of four types of sedentary behavior and five types of physically active behaviors were acquired from the UK biobank. The data for sedentary behaviors include watching TV (N=437,888), using computer(N=360,895), mobile phone use(N=310,555), and driving(N=456,972). The FinnGen collaboration provides summary statistics for psoriasis, which included 216,752 European individuals (4,510 cases and 212,242 non-cases). Inverse-variance weighted (IVW), MR-Egger, and the weighted median were used to assess causality. IVW was a key method to estimate the correlation between exposure and outcome. The results were analyzed using R and considered a significant at p < 0.05.

Results: There were strong genetic causal relationships between psoriasis and TV watching. Watching TV was identified as the risk factor of psoriasis by

POS0942

THE SIGNIFICANCE OF PRE-SCREENING OF SUBCLINICAL MALIGNECIES BEFORE THE TREATMENT OF BIOLOGIC AGENTS OR JAK INHIBITORS TO CONNECTIVE TISSUE DISEASE PATIENTS

Keywords: Targeted synthetic drugs, bDMARD, Malignancy

K. Misaki1,2, Y. Mako1,2, T. Okada1,2, Y. Tarutani1,2, M. Yabeh1,2, K. Inoue1,2, Y. Tanaka1,2, K. Misaki1,2, Y. Mako1,2, T. Okada1,2, Y. Tarutani1,2, M. Yabeh1,2, K. Inoue1,2, Y. Tanaka1,2, K. Misaki1,2, Y. Mako1,2, T. Okada1,2, Y. Tarutani1,2, M. Yabeh1,2, K. Inoue1,2, Y. Tanaka1,2

The patient characteristics were as follows: Median age: 68 yr.(n=336). (RA:69 yr., SLE:48yr., SpA:63yr., Vasculitis:73yr., Overlap syndrome:70yr., others:57yr.). The prevalence of benign tumors and malignant tumors were 24.7% (n=83, median age:68yr.) and 5.1% (n=17, median age:74yr.<Max:89yr.). Min:50yr.＞, respectively. The details of the malignancies were prostate cancer (n=19, 35.3%), uterus or ovarian cancer (n=3, 17.6%), gastric cancer (n=3, 17.6%), colon cancer (n=2, 11.8%), breast cancer (n=1, 5.9%), lung cancer (n=1, 5.9%) and thyroid cancer (n=1, 5.9%). Most of the age complicated with cancers was 80yr (median) except for those of uterus or ovarian cancer:50yr (median). Eleven patients (64.7%) among cancer bearing patients (n=17) successfully administered Bio or JAKi before radical operation such as endoscopic or surgical resection and all of the 11 patients achieved clinical remission.

Conclusion: Subclinical malignancies were detected by means of intensive pre-screening examinations. The most common cancer was prostate cancer, subsequently uterus or ovarian cancer and gastric cancer. It is important to perform pre-screening examinations before an aggressive therapy such as Bio or JAKi to CTD patients.

IVW (OR =2.11; 95% CI, 1.35-3.30, P=1.02E-03), identical to MR-Egger and the weighted median analysis. Pleiotropy and heterogeneity were not found by Cochran’s Q (P =0.14) and egger-intercept (P=0.43), suggesting these findings were reliable. In contrast, there was no causal relationship between the other activities and psoriasis (P > 0.05).

Figure 1a: Mendelian randomization results for gene-level causality between physical activity (PA) and psoriasis were evaluated by the odds ratio (OR) values of IVW, MR Egger, and Weighted median. Scatter plots (A), funnel plots (B), leave-one-out analysis (C), and forest plot (D) present TV watching as a risk factor for psoriasis. IVW, inverse-variance weighted; CI, confidence interval; SNP, single nucleotide polymorphisms.

Conclusion: Our findings reveal that TV watching is an apparent risk factor for psoriasis. It provides psoriasis patients with a piece of advice that they should lessen their sedentary time and boost physical activity.

POSO945

ILD PROGRESSION ON STANDARD OF CARE VARIES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE

Keywords: Prognostic factors, Organ damage, Lungs

E. Langballe1,2, P. P. Diep1,3, H. Andersson1, C. Brun4,5, H. Fretheim1, T. Garen1, R. Gunnarsson1, O. Midveldt1, O. Molberg1,2, O. Palm1,2, S. Reiseter1, T. M. Aalokken1, O. DIster1, A. M. Hoffmann-Vold1,6, 1 Oslo University Hospital, Rheumatology, Oslo, Norway; 2University of Oslo, Faculty of Medicine, Oslo, Norway; 3Oslo University Hospital, Respiratory Medicine, Oslo, Norway; 4Careggi University Hospital, Department of Experimental Medicine, Division of Rheumatology, Firenze, Italy; 5University Hospital of Zurich, Rheumatology, Zürich, Switzerland; 6Martina Hansens Hospital, Rheumatology, Gjettum, Norway; 7Oslo University Hospital, Radiology, Oslo, Norway

Background: A subset of patients with connective tissue disease associated interstitial lung disease (CTD-ILD) progresses. These patients have been included in clinical I LD trials as a group despite their different underlying diseases. It has not been studied whether this basket approach of pooling different CTD-ILDs is valid, e.g., if the disease course of the ILDs depends on the underlying CTD. In addition, the impact of immunosuppressive treatment, which CTD-ILD patients receive for I LD or other organ manifestations as a standard of care, is not fully understood.

Objectives: To assess ILD progression in patients with CTD-ILDs on standard of care treatment.

Methods: CTD-ILD patients (N=504) from a Norwegian and Swiss cohort fulfilling the respective classification criteria of the underlying CTD with ILD diagnosed on HRCT were included. Data were extracted from prospectively collected local electronic medical records. Additional data were extracted from an existing database of prospectively collected medical records. Change in absolute FVC's predicted over 12 months was calculated. In addition, ILD progression was assessed over 12 months on standard of care treatment, defined as:
Results: The total CTD-ILD cohort of 504 patients included 231 (46%) systemic scleroderma (SSc)-ILD, 91 (18%) primary anti-synthetase syndrome (ASS)-ILD, 82 (16%) rheumatoid arthritis (RA)-ILD, 57 (11%) primary Sjögren syndrome (pSS)-ILD and 43 (9%) mixed connective tissue disease (MCTD)-ILD patients (Table 1). Mean absolute change in FVC% over 12 months was for the entire cohort -0.74% (range -34 to +42%), 57 (13.7%) had an FVC decline ≥10% and 47 (12%) fulfilled the guideline criteria. ILD progression varied between the diagnoses, with SSc-ILD and pSS-ILD showing the strongest absolute FVC decline over 12 months and the highest percentage of progressive patients defined by the 2022 guideline. Additionally, patients with SSc-ILD and MCTD-ILD had more frequent FVC ≥10% events (Table 1). Overall, 240 (62.8%) patients were treated with immunosuppressives (table 1). There was no difference between patients treated and not treated in absolute FVC decline (OR 1.00, 95%CI 0.98-1.02, p = 0.705), and in the percentage of progressive patients according to the guideline criteria (OR 1.00, 95% CI 0.54-1.86, p = 0.996). However, there was less FVC decline ≥10% (OR 0.51, 95% CI 0.28-0.90, p = 0.022) in patients treated with immunosuppressives. Patients with SSc-ILD (11% vs 20%, p = 0.059) and pSS-ILD (8% vs 19%, p = 0.329) showed numerically less FVC decline ≥10%. The different CTD diagnoses had different patterns of treatment with immunosuppressives, with the majority of RA and ASS-ILD being treated (Table 1).

</tbody>
</table>

Conclusion: In this CTD-ILD cohort, both undergoing CTD and immunosuppressive treatment seemed to be associated with different patterns of ILD progression over a 12-month period. This has implications for the enrichment for progressive disease and inclusion of CTD-ILD patients into clinical trials.

DOI: 10.1136/annrheumdis-2023-eular.4735
Subclinical synovitis at baseline were associated with resolution of subclinical synovitis.

Background: Subclinical synovitis is a relatively common ultrasound (US) finding in individuals at-risk of rheumatoid arthritis (RA) (33%) [1]. It is associated with the development of inflammatory arthritis (IA); which often results in physicians prescribing disease modifying anti-rheumatic drugs (DMARDs) in the absence of clinical inflammation. Prediction of resolution of these changes may prevent overtreatment in a number of these patients.

OBJECTIVES:
1) To assess reversibility of subclinical synovitis in individuals at risk of RA, within 12 months' time.
2) To investigate factors associated with resolution of subclinical synovitis.

Methods: A single centre, prospective, observational study recruited anti-cyclic citrullinated peptide (anti-CCP) antibody positive at-risk individuals with a new musculoskeletal complaint, but no clinical synovitis. US scans of wrists, metacarpophalangeal joints, proximal interphalangeal joints and metatarsophalangeal joints were performed at baseline. Those with subclinical synovitis (grey scale (GS) ≥1 and power doppler (PD) ≥1) in at least one joint were then selected. The following variables were collected: gender, age, smoking exposure, anti-CCP titre, the presence of rheumatoid factor, antinuclear antibodies (ANA) and shared epitope, levels of CRP (mg/dL) and ESR (mm/h), minutes of exercise, presence of anti-topoisomerase (Topo I) antibodies or evidence of ILD at high-resolution computed tomography (HRCT). Analyses were restricted to those with ILD at HRCT. PODs at 5 years, defined by absolute changes in forced vital capacity (FVC) % of predicted values, were explored by latent class mixed models (LCMM). Survival analysis (lung-related events) was also conducted on evolution data.

Results: 473 patients at risk for SSc-ILD were identified, of those 424 (89.6%) had evidence of ILD at HRCT; 152 (34.2%) were classified as T1 (yearly change in FVC > 0.05%), 27 (5.9%) as T2 (yearly change in FVC between 0.01% and 0.05%), and 31 (6.7%) as T3 (yearly change in FVC < 0.01%). HRCT analyses were restricted to those with ILD at HRCT. PODs at 5 years, defined by absolute changes in forced vital capacity (FVC) % of predicted values, were explored by latent class mixed models (LCMM). Survival analysis (lung-related events) was also conducted on evolution data.

Keywords: Systemic sclerosis, Lungs, Prognostic factors

Disclosure of Interests: None Declared.

Acknowledgements: NIL.

Background: Intestinal lung disease (ILD) is a severe complication of systemic sclerosis (SSc) that may lead to irreversible loss of lung function and increased mortality. Patterns of disease progression (PODs) in SSc-ILD are poorly characterized.

Objectives: To define PODs in SSc-ILD patients that may have clinical implications for patient stratification and clinical trial design.

Methods: Patients with SSc at risk for ILD were recruited in 6 tertiary referral centers. Inclusion criteria were: a) Disease duration < 5 years at the time of the first pulmonary function test (PFT); b) absence of anti-centromere antibodies; c1) diffuse cutaneous subset (dcSSc) OR c2) limited cutaneous subset (lcSSc) with either presence of anti-topoisomerase (Topo I) antibodies or evidence of ILD at high-resolution computed tomography (HRCT). Analyses were restricted to those with ILD at HRCT. PODs at 5 years, defined by absolute changes in forced vital capacity (FVC) % of predicted values, were explored by latent class mixed models (LCMM). Survival analysis (lung-related events) was also conducted on evolution data.

Results: 473 patients at risk for SSc-ILD were identified, of those 424 (89.6%) had evidence of ILD at HRCT and were selected for in-depth analyses. Baseline demographic and clinical characteristics are reported in the Table 1. Multivariable Cox regression showed that FVC values (HR = 0.992; 95% CI = 0.989 – 0.995, p < 0.001) as well as the yearly change in FVC (HR = 0.961, CI95 = 0.932 – 0.992, p < 0.05) were predictive of 10-years mortality. LCMM analysis discovered 5 PODs (Figure 1); the majority of patients showed a stable FVC or slow decline in lung function. Patients with stable improvement had higher age and shorter disease duration compared to patients with sharp deterioration (SS < 10 vs ≥ 15 years, both p < 0.05) and a lower exposure to immunosuppressants (68.4% vs 85.3%); no other difference in clinical or demographic variables was observed among classes. Ten-years survival estimates were lower in patients with sharp (75.1%) or slowly-declining lung function (79.8%) compared to the other groups (>80%) with no event in the sharp improvement class (log-rank p = 8*10^-4). The predictive capability of LCMM classes was 0.766 ± 0.03 as measured by Harrel’s C-index.

2Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: The temporomandibular disorders (TMDs) encompass a heterogenous group of inflammatory and degenerative diseases which impair the masticatory function causing local pain and dysfunctional consequences of the temporomandibular joint (TMJ) [1].

Objectives: To systematically review the literature concerning TMDs in immune-mediated rheumatic diseases (IMRDs) of the adult and synthesize their burden in multiple domains of clinical interest: patient-reported outcomes (PROs), frequencies of signs on physical examination, imaging features, histological findings, and risk factors for their development in patients with IMRDs.

Methods: A literature search on PubMed Central, Embase and Cochrane Library databases was performed, until June 2022, for studies including TMJ outcomes in IMRDs patients compared with healthy controls, other rheumatic diseases or databases was performed, until June 2022, for studies including TMJ outcomes. Ten papers (18%) evaluated TMDs in spondylarthritides (SpA) reporting a prevalence of symptoms and signs in 12-80% of patients with higher TMDs prevalence in patients with radiographic spine involvement, skin psoriasis and HLADRBI*01 positivity. Among autoimmune connective tissue diseases (CTDs), systemic sclerosis (SSc) displayed the highest evidence of TMDs PROs and clinical findings (20-93%), followed by systemic lupus erythematosus (SLE) in 18-85%, mixed connective tissue disease (MCTD) in 31-63%, primary Sjögren’s syndrome (pSS) in 24-54% and idiopathic inflammatory myopathies (IIMs) in 4-26%. In SSc and SLE, TMDs were more frequent in patients with higher disease activity and duration, correlating with the extent of skin fibrosis in SSc and with renal involvement in SLE.

Conclusion: TMDs in IMRDs display a significant relevance in the rheumatological clinical practice even if they are often overlooked. This burden is epidemiologically important in terms of PROs and clinical findings which correlate with disease activity in RA, SpA, SSc and SLE. The early recognition and multidisciplinary management of TMDs is warranted and should be aimed at hindering the TMJ structural damage maximizing the quality of life of patients.

Legend: NA: not assessed. See the text for the other abbreviations.
and prior steroid use, tenosynovitis and higher CDAI remained associated with requiring DMARDs and prior chemotherapy was associated with lower likelihood of DMARDs (Table 1). Higher CDAI was also associated with higher likelihood of requiring corticosteroids (1.11 p<0.012). Those positive for rheumatoid factor had a lower likelihood of requiring steroids (0.168 p<0.013). Combination anti-CTLA-4/PD-1 (5.07 p<0.036) therapy and being on steroids at baseline (5.28 p<0.031) were associated with a higher likelihood of persistent IA; there were trends for higher CDAI and tenosynovitis associating with persistence.

Conclusion: Higher levels of disease activity and having tenosynovitis were associated with a higher likelihood requiring immunosuppression beyond corticosteroids for ICI-IA while those treated previously with chemotherapy were less likely to require additional immunosuppression. The presence of risk factors for severe disease at baseline may indicate higher initial steroid dose or earlier adoption of immunosuppression to improve outcomes.

Background: Few studies on the risk of incident major adverse cardiac and cerebrovascular events in presarcopenic and sarcopenic patients have been reported, with contradictory results [1].

Objectives: The objective was to assess the association between presarcopenia and sarcopenia, and higher risk of major adverse cardiac and cerebrovascular events.

Methods: It was a retrospective analysis of the UK Biobank prospective cohort, using data collected between 2006 and 2021. Community-dwelling Caucasian participants aged 37 to 73 years were included if values for Handgrip Strength and Skeletal Muscle Index were available, and if no history of a major adverse cardiac and cerebrovascular event was reported. Exposure was assessed using the European Working Group on Sarcopenia in Older People 2 (EWGSOP2) criteria [2]. Muscle strength was measured using Handgrip Strength, and muscle mass using the Skeletal Muscle Index (from impedance data). Presarcopenia was defined as low Handgrip Strength with normal Skeletal Muscle Index; whereas sarcopenia was defined as low Handgrip Strength with low Skeletal Muscle Index. Participants with presarcopenia and sarcopenia were merged to form a single group (PreSarc) and were compared against a group of non-sarcopenic participants (NonSarc). To determine whether sarcopenia and/or presarcopenia were predictors of major adverse cardiac and cerebrovascular events (composite events: acute myocardial infarction, angina pectoris, ischemic or hemorrhagic stroke, and transient ischemic attack, whether fatal or non-fatal).

Results: A total of 406,411 participants (women: 55.7%; median age: 58.0 (IQR: [50.0; 63.0]) years) were included. At baseline, 18,612 participants (4.6%) were allocated to the PreSarc group. Over a median follow-up of 12.1 years (IQR: [11.4; 12.8]), 28,300 participants (7%) were diagnosed with at least one event. Compared to NonSarc, PreSarc was significantly associated with a higher risk of major adverse cardiac and cerebrovascular events (fully adjusted HR=1.25, 95%CI=[1.12; 1.38]) and HR=1.58, 95%CI=[1.31; 1.90], respectively.

Conclusion: In a community-dwelling population, the risk of major adverse cardiac and cerebrovascular events was higher in both presarcopenic and sarcopenic participants.

Objectives: Progressive pulmonary fibrosis (PPF) is characterized by deterioration of respiratory symptoms, lung function decline and progressive fibrosis on high-resolution computed tomography (HRCT). It is associated with poor prognosis. Patients with connective tissue disease-related interstitial lung disease (CTD-ILD) may also develop PPF and need intensified clinical management. However, different criteria for PPF are used in trials (i.e. INBUILD and RELIEF) and the ATS/ERS/JRS/ALAT 2022 guideline.[1-3] This variety in criteria complicates study comparison and clinical implication.

Objectives: To explore the prognostic relevance for mortality of different PPF criteria in patients with CTD-ILD.

Methods: This is a single center retrospective cohort study in patients with CTD-ILD or interstitial pneumonia with autoimmune features between 2005 and 2021. The prognostic relevance was compared between the INBUILD criteria[1], the ATS/EURS/JRS/ALAT 2022 criteria[3], and the simplified progressive fibrosing (simplified PF) criteria used in a previous cohort (≥10% relative decline in FVC, ≥15% relative decline in DLCO, or progression of fibrosis on HRCT within two years)[4] in the time-dependent receiver operator characteristic model.

Results: The cohort consisted of 230 patients. The median age was 63 years (IQR 54—69), and 122 (53%) were female. The most prevalent CTD was rheumatoid arthritis (n=77, 33%), followed by 38 (17%) patients with idiopathic inflammatory myopathies and 33 (14%) with primary Sjögren’s syndrome. Various HRCT patterns were observed at baseline: UIP in 63 (27%) patients, fibrotic NSIP in 21 (9%), cellular NSIP in 25 (11%), mixed NSIP in 79 (34%), OP in 34 (15%), two (1%) mixed NS/IP, and other patterns in six. The median follow-up period was 6 (3—9) years. Mortality risk was independently associated with age (adjusted HR 1.07, p < 0.001), smoking history (adjusted HR 1.90, p = 0.045), extent of fibrosis on HRCT at baseline (adjusted HR 1.05, p = 0.018) and baseline DLCO % of predicted (adjusted HR 0.97, p = 0.013). PFF was observed in 61 (27%) patients meeting INBUILD criteria, 53 (23%) meeting ATS/EURS/JRS/ALAT 2022 criteria, 136 (59%) meeting simplified PF criteria and 125 (54%) when using simplified PF criteria with a threshold for HRCT ≥ 5% increase in the extent of fibrosis. The prognostic relevance for mortality did not differ between simplified PF criteria, INBUILD and ATS/EURS/JRS/ALAT 2022 criteria; the prognostic relevance improved when the simplified PF criteria defined HRCT progression with a ≥5% increase in fibrosis. (Figure 1)

Conclusion: Higher age, smoking, increased extent of fibrosis and low baseline DLCO were associated with poor prognosis. The prognostic value was similar between the different PPF criteria and increased during the first three years and achieved a plateau thereafter.

REFERENCES:
MPN with or without AID. The prevalence of TET2 mutations was higher in the AID cohort (21/65, 32% versus 208/993, 22%), although not reaching statistical significance (p=0.08). After a median follow-up of 8.3 years (7.7-14.3) years, the association with AID did not reach statistical significance in survival free-patient (p=0.37) or secondary myelofibrosis-free survival (p=0.91).

Conclusion: Our data suggest that the prevalence of AID is similar in MPN patients to that of the general population, and that the distribution and presentation of AID in MPN patients is also similar. TET2 mutations are highly prevalent in MPN patients with AID suggesting a shared pathophysiology. Additional mechanistic studies are needed to further decipher a potential TET2-mediated common pathophysiology. The association with AID did not impact MPN patients’ outcome.

POS0954 CLINICAL FEATURES AND GENOMIC LANDSCAPE OF MYELOPROLIFERATIVE NEOPLASMA (MPN) PATIENTS WITH AUTOIMMUNE AND INFLAMMATORY DISEASES

Keywords: Outcome measures, Genetics/epigenetics, Descriptive studies

Background: Autoimmune and inflammatory diseases (AID) are associated with myeloid malignancies[1], and include both organ-specific diseases and systemic inflammatory disorders. While the occurrence of associated AID reaches up to 15-20% in myelodysplastic neoplasms (MDS) patients[2,3], its prevalence in the context of myeloproliferative neoplasms (MPN) remains unknown. In patients with a history of AID, the risk of developing MPN was increased[4], suggesting a correlative link between the two disorders, but data regarding the characterization of AID in MPN patients remain scarce and the lack of studies prevents from identifying potential risk traits that may underlie a common physiopathology.

Objectives: We conducted a single center retrospective study to describe the prevalence, clinical and biological features of AID in MPN patients. We also reported the mutational landscape of MPN with associated AID, along with its prognostic impact.

Methods: All patients with a diagnosis of Philadelphia-negative MPN according to the World Health Organization’s criteria, followed between January 2011 and January 2021 in our center were included. Clinical and biological characteristics at the time of diagnosis and follow-up were collected. Next-generation targeted sequencing was performed targeting a panel of 36 genes involved in myeloid malignancies. AID diagnosis was based on recommended international criteria specific to each AID. Patients with interferon-alpha-induced AID were excluded from this study.

Results: A total of 1541 MPN patients were included, including 95 (6%) patients with AID who were compared to the remaining 1446 (94%) patients without AID. Median age was 51.6 [6.6; 98.3] years at MPN diagnosis in the whole cohort. Female patients were predominant within the AID group (82 (65%) versus 773 (54%), p=0.03). Within the AID cohort, a total of 103 diagnoses of AID were reported in 95 patients, including 48 organ-specific AID (47%) (autoimmune hypothyroidism (n=33), inflammatory bowel diseases (IBD, n=7), neuroinflammatory disorders (n=4), autoimmune cytopenia (n=2), golferunileuphthrin (n=1) and pernicious anemia (n=1)), 13 inflammatory arthritis (13%), 9 connective tissue diseases (9%), 9 dermatosis (9%), 6 systemic vasculitis (8%) and 18 unclassified AID (17%). Molecular sequencing was performed in 998/1541 (65%) patients and the prevalence of driver and additional mutations did not differ between the

Background: Neurosarcoidosis (NS) is a serious and relative uncommon complication of sarcoidosis [1]. Data on incidence is scarce and varies worldwide. Objectives: To estimate NS epidemiology in Northern Spain.

Methods: Patients diagnosed with sarcoidosis at a University hospital in Northern Spain, between January 1999 and December 2019 were assessed. Sarcoidosis diagnosis was established according to ATS/ERS/WASOG criteria as follows: compatible clinical and radiological presentation, histopathologic confirmation, and exclusion of other granulomatous diseases. NS was diagnosed according to the NS Consortium Consensus Group [2]. Demographic and clinical data were collected. The incidence of sarcoidosis between 1999-2019 was estimated by gender, age, and year of diagnosis.

Results: NS was observed in 30 of 234 (12.8%) (19 women/11 men) (mean age: 55.0±15.8 years) patients with sarcoidosis. The underlying neurological manifestations were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20.0%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10.0%) and aspecific meningitis (n=3, 10.0%). A comparison between different geographical areas is summarized in Table 1. There are wide variations in frequency (US:4.8% to France:33.9%), gender predominance and age at diagnosis (31 to 55 years) depending on the geographical area. Nevertheless, most of the patients were diagnosed in the 5th decade of life. Annual incidence of NS in our population area in the 1999-2019 period was 0.11 per 100,000 people, 95% (Cl:0.11-0.26); 0.08 (0.07-0.24) in men, 0.13 (0.09-0.24) in women. There were variations in annual incidences, ranging from a minimum value of 0.08 in 2013-2014 to a maximum of 0.19/100,000 people in 1999-2000. A downward trend in annual incidence over time was observed. Nevertheless, the correlation was weak (r²=0.1135) (Figure 1).

Conclusion: The epidemiological characteristics of NS is very different in frequency. Frequency estimated in this study was similar to that of other countries. References: [1] Riancho-Zarrabeitia L, et al. Clin Exp Rheumatol 2014; 32:275-84. PMID:24321604.

**PERSISTENCE ON TREATMENT AND SAFETY OF TNF-ALPHA INHIBITORS BIOSIMILARS COMPARED TO ORIGINATORS: AN OBSERVATIONAL STUDY ON THE FRENCH NATIONL HEALTH DATA SYSTEM**

**Keywords:** Real-world evidence, Safety, bDMARD

**Methods:** We used data from the French National Health Data System to identify IFX, ETA and ADA initiators from the date of marketing in France of the first biosimilar of each molecule (01/2015, 05/2016 and 10/2016 respectively) and until 30 June 2021. Patients were then followed during one year. Treatment persistence was defined as the duration without treatment discontinuation (60 days gap plus theoretical coverage of the molecule without treatment delivery) or modification (for another biologic treatment), censoring the follow-up at 1 year of follow-up, death or intra-molecule switch (for at least 2 consecutive deliveries). Persistence was compared between users of the originator product and biosimilars by Cox regressions and comparison of cumulative risks of event using Kaplan-Meier survival probabilities at 1 year, weighting the populations on the inverse probability of treatment. Analyses were performed by molecule, by disease treated and by biosimilar product used. Adverse treatment events, including infections, major cardiovascular events, immunology disorders, cancers, death and all-cause hospitalization, were also described by comparing originator and biosimilar event rates, including infections, major cardiovascular events, immunology disorders, cancers, death and all-cause hospitalization, were also described by comparing originator and biosimilar event rates.

**Results:** A total of 86,776 patients were included in the study (22,670, 24,442 and 39,664 IFX, ETA and ADA initiators respectively). Within molecules, subject characteristics at inclusion were very similar between originator and biosimilar products. After weighting, the hazard ratios (HR) and relative risks of treatment discontinuation or modification in biosimilar versus originator products were close to 1 or below 1, with confidence intervals covering 1, except for ADA ABP501 which showed a minor increased risk of non-persistence compared to ADA originator in inflammatory bowel diseases (HR 1.24 [1.09-1.41] and 1.22 [1.03-1.44] in CD and UC). Crude adverse event rates were very similar between originator and biosimilar products. After weighting, the hazard ratios (HR) and relative risks of treatment events, including infections, major cardiovascular events, immunology disorders, cancers, death and all-cause hospitalization, were also described by comparing originator and biosimilar event rates.

**Conclusion:** Our study shows reassuring results regarding the persistence and safety of biosimilars compared to the originator anti-TNF alpha product in all licensed indications. Further studies need to be carried out to confirm these results, and to investigate the switch context.

ASSOCIATION BETWEEN AIR POLLUTANTS AND INITIATION OF BIOLOGICAL THERAPY IN PATIENTS WITH ANKYLOYSING SPONDYLITIS: A NATIONWIDE, POPULATION-BASED CASE-CONTROL STUDY

Keywords: Epidemiology, bDMARD, Spondyloarthrits

C. M. Kao1, H. H. Chen1,2, Taichung Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taichung City, Taiwan, Republic of China; Taichung Veterans General Hospital, Division of General Internal Medicine, Department of Internal Medicine, Taichung City, Taiwan, Republic of China

Background: Ankylosing spondylitis (AS) is a systemic inflammatory disease and the first-line pharmacological therapy includes non-steroidal anti-inflammatory drugs (NSAIDs) for peripheral joint involvement and immunosuppressants including methotrexate (MTX) and sulfasalazine (SSZ) for peripheral arthritis[1]. Biological therapy under National Health Insurance (NHI) reimbursement is indicated for AS patients without adequate response to first-line therapy in Taiwan. Initiation of biologics such as tumor necrosis factor inhibitors and interleukin-17 inhibitors may act as a proxy for high disease activity. Outdoor air pollution has been found to trigger a systemic inflammatory response[2]. Therefore, we hypothesized that air pollutants may be associated with biologics use in AS patients.

Objectives: To investigate the association between air pollutants and initiation of NHI-reimbursed biologics indicated for high disease activity in patients with AS.

Methods: We conducted a nationwide case-control study using the Taiwan National Health Insurance Research Database, and incident AS patients from 2003 to 2013 were identified. We excluded those with a diagnosis of rheumatoid arthritis, those treated with biologics including etanercept, adalimumab, and golimumab before the first date of visit with AS diagnosis, and those without outpatient visits after 2009. We identified all AS patients initiating biologics for active AS as biologics cases, and non-biologics controls for those who didn’t. Index date was designated as the date of initiation of first biologics for cases and the date of first outpatient department visits each year for controls. We matched both groups at a 1:4 ratio for gender, age at first biologic initiation (±3 years), year of first AS diagnosis, and disease duration (±0.3 year), and finally included 584 biologics cases and 2336 matched controls.

With aid of a spatio-temporal model built by a deep-learning approach, we used the hourly concentrations of ambient air pollutants from 60 air quality censoring stations observed in the elderly-onset group.

Results: Among all elderly-onset cases, the proportion of elderly-onset AOSD patients significantly increased from 2000s, while hospitalization due to infectious complications was more frequently observed in the elderly-onset group.

Figure 1. Trends in the proportion of young and elderly-onset AOSD

Y. Sakai1, Y. Kondo2, S. Kasaiz2, S. Kojima2, H. Tamaiz2, Y. Kaneko2. 1Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology; Tokyo, Japan; 2Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology; Tokyo, Japan.
Conclusion: The frequency of patients with elderly-onset AOSD has been increasing in recent years. Patients with elderly-onset AOSD had significantly characteristic clinical features in comparison with those with young-onset AOSD. Adolescents were more susceptible to infectious complications as well as AOSD flare in patients with elderly-onset AOSD.

POS0963 PERINATAL DEATHS IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Results: A descriptive, observational, cross-sectional study was conducted; we selected patients with history of PL from 2017 to date. Clinical records from the Pregnancy and Rheumatic Diseases Clinic (CEER) from the Hospital University “Dr. José Eleuterio González” in México were revised to obtain ARDs, obstetric clinical history, socioeconomic studies and the Edinburgh Postnatal Depression Scale (EPDS) scores.

Background: The grief over the death of a baby around the date of birth registers becomes a traumatic event and generates emotional distress, changes in sleep and eating patterns, vulnerability to illness and an increased risk of maternal mortality up to two years following the loss [1]. In Mexico during 2021, 23,000 fetal deaths were registered: 83.5% were before birth, 15.3% during birth and 1.2% was not specified [2]. Women with autoimmune rheumatic diseases (ARDs) have greater risk of perinatal loss, the correct psychological approach is fundamental in the grieving process when these events occur.

Objectives: Describe the frequency and characteristics of the perinatal loss (PL) in women with ARDs.

Methods: A descriptive, observational, cross-sectional study was conducted; we selected patients with history of PL from 2017 to date. Clinical records from the Pregnancy and Rheumatic Diseases Clinic (CEER) from the Hospital University “Dr. José Eleuterio González” in México were revised to obtain ARDs, obstetric clinical history, socioeconomic studies and the Edinburgh Postnatal Depression Scale (EPDS) scores.

POS0964 RELATIONSHIP BETWEEN PM2.5 PARTICLE FROM HOUSEHOLD AIR POLLUTION AND INFLAMMATORY AND EPIGENETIC MARKERS IN RHEUMATIC PATIENTS FROM AN INDIGENOUS COMMUNITY IN CHIAPAS: BASELINE STUDY

Results: From the 79 patients that have been admitted to the clinic, 16 (20%) had PL. The ARDs more frequent was Rheumatoid Arthritis (RA) with 7 (43.8%) patients, Systemic Lupus Erythematosus (SLE) with 6 (37.5%) and other diagnosis (Dermatomyositis, Antiphospholipid Syndrome and UCTD) with 3 (18.9%), other characteristics are displayed in table 1. Twelve of these patients have their ARDs active during their pregnancy, 4 of them didn't continue with their rheumatic treatment after the event. Regarding the PL 6 (37.5%) experienced the loss during the first trimester, 3 (18.7%) in the second trimester and 1 (6.2%) in the third trimester and 6 (37.5%) were neonatal losses. From all the pregnancies, 9 were not planned and 13 were desired. Grieving counseling was offered to the patients were asked to respond the EPDS; only 11 (69%) of them answered it and 3(27%) got a score greater than 13 (need for follow up of possible depressive symptoms). Of this deaths, one was in the second trimester and two were after birth. Scores greater than 13 were correlated with education, marital status, total number of PL and agreeing to the grieving counseling. No statistically significant correlation was found.

Conclusion: We have a 20% loss rate in our population. Women with ARDs that experienced one or more perinatal deaths could have greater risk to develop physical and emotional complications after the event. It's necessary to develop a proper guideline to treat our patients and prevent physical and emotional stress.

THE RISK OF INFLUENZA IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES-FOCUS ON PRIMARY SJÖGREN’S SYNDROME, POLYMYSITIS/DERMATOMYOSITIS AND SYSTEMIC SCLEROSIS

Keywords: Sjögren syndrome, Systemic sclerosis, Myositis

Chang1,2, Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China; 2School of Medicine, College of Medicine, Taipei Medical University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China

Background: Influenza vaccine is recommended in patients with most systemic autoimmune rheumatic diseases (SARDs). However, the risk of influenza was less studied in the SARDs other than rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Objectives: This study aimed to investigate the risks of influenza-related hospitalization in patients with SARDs, including primary Sjögren’s syndrome (pSS), polymyositis/dermatomyositis (PM/DM), systemic sclerosis (SSc), RA and SLE.

Methods: This is a nationwide population-based cohort study analyzing the National Health Insurance Database in Taiwan. Patients with catastrophic certification of each SARD were identified. The risks of influenza-related hospitalization in patients with each SARD were compared with their age- and sex-matched non-AIIRD cohort (1:2). Incidence rates (IR) with incidence rate ratios (IRR) in the AIIRDs were analyzed.

Results: Totally, 48,905 patients with RA, 24,143 patients with SLE, 16,891 patients with pSS, 2,633 patients with SSc and 2561 patients with PM/DM were identified, with basic characteristics shown in Table 1. The IR of hospitalization due to influenza was highest in patients with PM/DM (Figure 1) followed by pSS, SSc, SLE and RA. In comparison with their age- and sex-matched controls,

the risk was highest in patients with PM/DM with an IRR of 16.83, followed by patients with SSc, pSS, SLE and RA.

**Conclusion:** Patients with PM/DM, SSc, pSS, RA and SLE had significant increased risk of influenza-related hospitalization. In comparison with each matched controls, PM/DM, SSc and pSS cohorts had even higher IRR than that of the SLE and RA cohorts, whose risks of influenza and the benefit of vaccination were well-known. Considering the risk, patients with these SARDs should follow the recommendations to have influenza vaccine every year and further study about the benefit of vaccine in patients with DM/PM, SSc and pSS are needed.

**Acknowledgements:** NIL.

**Disclosure of Interests:** None Declared.

**Keywords:** Geographical differences, Registries, Epidemiology

**Background:** Rheumatic and musculoskeletal diseases (RMDs) have become leading causes of death (CODs)[1,2]. However, few study has provide an integrated overview of mortality burdens, leaving a care gap between region[3]. Therefore, estimates on mortality burdens of RMDs and their relationships with socioeconomic factors are essential for prioritizing health policies, especially in low-to-middle income countries (LMICs).

**Objectives:**

- To provide an integrated atlas of mortality-related health metrics of 9 RMDs, including RA, SpA, SLE, SS, IM, SSc, BD, TAK, and AAV.
- To illustrate the associations between disease burdens of RMDs and development indicators from multiple aspects.

**Methods:** A nationwide multicentre cohort was linked to Nation Mortality Surveillance System. RMD ascertainment was based on classification criteria, death case ascertainment was following ICD-10 codes. Data collection was conducted, followed by a 3-phase imputation and sensitivity analyses. CODs, SMRs, and life expectancies were estimated. A composite indicator, human development index (HDI), and indicators in economy, healthcare, and education were adopted as area-level socioeconomic status indicators.

**Results:** Between 2008 and 2021, 175 846 individuals were included (Figure 1). AAV, IIM, and SSc ranked top 3 diseases with the highest fatality rates over 10% and lowest survival rates within 10 years after the first diagnosis of RMDs. Principal immediate CODs in patients with RMDs are shown in Figure 1. Adjusted SMR was highest for TAK, followed by IIM, SSc, SLE, AAV, BD, and SS (Figure 1). The mortality risk of patients with RA was generally comparable with overall population. Early disease-onset is a risk factor of excess death in both male and female patients with CTDs. Higher HDI was associated with significant increases in mortality risks in both RA and SLE (SMR ratio 12.24 and 5.15 for 1-unit increase in HDI, p<0.001 and p=0.080) patients compared with region-specific general population. More medical institutions (SMR ratio 0.95 for 1 more medical institution per 10 000 resident population, p=0.005) and hospital beds (SMR ratio 0.35 for 1 more hospital bed per 100 resident population, p=0.131) were protect factors of excess mortality in SLE. In overall patients, SS, SLE, and AAV, IIM and SSc, had mild, moderate, and strong associations with the loss in life expectancy, respectively (Figure 1).

**Conclusion:** This study relied on the biggest nationwide register-based cohort of more than 170 000 patients with RMDs confirmed by rheumatologists. We observed that mortality risk (up to 4.5 times) and loss of life years (up to 25 years at the age of 10) in patients with RMDs can be in substantial excess versus general population. Additionally, our study provides the first systematic account that the mortality burdens of RMDs have a complicate relationship with the level of regional deprivation. Increasing mortality burdens associated with RMDs implied the relative insufficiency of capacity building of diagnosis and treatment in RMDs in LMICs.

ANCA-ASSOCIATED VASCULITIS INCIDENCE IN A NORTHERN SPANISH HEALTH REGION, 1994-2022: A POPULATION-BASED STUDY

Keywords: Descriptive studies, Vasculitis, Epidemiology

S. Al Fazazi 1, A. Herrera-Morant 1, V. Calvo-Río 2, M. Renuncio Garcia 3, G. Escagado Caggas 4, M. Rodriguez Vidriales 1, R. Blanco 5, Hospital Universitario Puerta del Mar. Rheumatology, Cádiz, Spain; 2Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 3Marqués de Valdecilla University Hospital, Immunology, Santander, Spain; 4Marqués de Valdecilla University Hospital, Nephrology, Santander, Spain

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV) includes granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA). Precise estimation of the incidence of AAV has been difficult due to the absence of reliable diagnostic criteria.

Objectives: To estimate the incidence in a Northern Spanish population-based cohort.

Methods: Population-based study of 132 patients diagnosed with small vessel vasculitides between 1994 and 2022 in a tertiary hospital. Finally, 98 patients were included as AAV according to ACR/EULAR 2022 criteria [1]. Incidence was estimated by gender, age, and year of diagnosis.

Results: AAV was diagnosed in 98 (49 women/49 men) patients: GPA (n=47, 48%) MPA (n=37,37%) and EGPA (n=14, 14%). Annual incidences were estimated in AAV (Figure 1). GPA annual incidence in our population area in the 1994-2022 period was 2.81 per 1,000,000 people, 95% CI: 3.77-1.85 in males and 2.80 in females. An upward trend in incidence over time was observed with rates ranging from 1.68 in 1994 to 6.84 in 2022 (weak correlation; r=0.2729). On the other hand, MPA annual incidence was 2.23 per 1,000,000 people (1.93 in males and 2.46 in females). Rates ranged from 1.88 in 1994 to 1.71 in 2022 with an upward trend over time (very weak correlation; r=0.0746). In the case of EGPA, annual incidence was 0.83 per 1,000,000 people, 95% CI: 1.72-0.06 (2.74 in males and 0.30 in females). As in the other types of AAV, there was an upward trend over time with variations of from 1.88 in 1994 to 3.42 in 2022 (weak correlation; r=0.3335). A comparison between different geographical areas is summarized in Table 1. Wide variations in annual incidence per million were observed in all AAV (GPA 2.1-13; MPA 2.23-10.4; EGPA 0.64-2.7). The highest annual incidence of all AAV was observed in northern countries and central Europe while the lowest in Southern Europe.

Conclusion: There seems to be a progressive increase in incidence of AAV over the years in the studied population. Annual incidence in our population was similar to that of other southern European countries.

Background: There is a lack of data on adherence in axial spondyloarthritis (axSpA). It is estimated between 28.2 ± 70.6% by the largest study currently available [1]. Many factors may influence adherence, among them psychological factors.

Objectives: The objectives were to assess adherence to biological disease-modifying anti-rheumatic drug (bDMARDs) and the impact of catastrophizing, fibromyalgia, anxiety, and depression in a cohort of patients with axSpA.

Methods: A multicenter cross-sectional study was conducted in five departments of Rheumatology in France. Inclusion criteria were axSpA according to the ASAS criteria, and treatment by bDMARDs. Patients completed an anonymous self-questionnaire including demographic data, disease activity scores, HADS, and Pain Catastrophizing Scale (PCS). Rheumatologists completed an independent medical questionnaire collecting the disease-related data.

Results: 500 patients with axSpA were enrolled into the study between June 2021 and June 2022. Patients had a mean age of 49.5 ±13.8 years and 53.2% were male. They were treated by anti-TNF, anti-IL17 or anti-IL12-23 in 85.8%, 13.2% and 1% of cases, respectively. Forty-three percent of the patients were adherent (GS=0) and 50.8% were non-adherent (GS ≥1). The prevalence of catastrophizing, fibromyalgia, anxiety, and depression in our study was 17.2%, 21.4%, 25.6% and 11.0%, respectively. Patients with best adherence were older (mean age: 53.26 ± 13.3 with GS=0 vs 45.85 ± 13.4 years with GS>0; p<0.001) and had a lower level of education (OR 1.84; 95% CI 1.15-2.95; p=0.015). Patients with anxiety and catastrophizing had a lower adherence (OR 1.53; 95% CI 1.02-2.30; p=0.05) and a higher depression score (OR 3.27; 95% CI 1.00-2.58; p=0.05, respectively). Adherence was not different between male and female patients, although female patients with axSpA had more catastrophizing (OR 1.84; 95% CI 1.15-2.95; p=0.015), fibromyalgia (OR 3.27; 95% CI 2.075-16; p<0.0001) and anxiety (OR 2.26; 95% CI 1.50-3.41; p<0.0001). In multivariate analysis, low adherence was associated with younger age (OR 0.96; 95% CI 0.85-0.98; p<0.001) and anxiety (OR 1.72; 95% CI 1.05-2.81; p=0.03).

Conclusion: Half of axSpA patients were non-adherent to bDMARDs, especially among young people, catastrophizers and patients with anxiety. We recommend that practitioners screen for these psycho-cognitive factors and manage them very carefully.

patients with ILD; no gender difference was evident. Compared with Caucasians, East and SEA (OR 5.14, 95% CI 2.59, 10.21) patients were up to 10 times more likely to be diagnosed with ILD. Controlling for racial groups, age and gender, IIM patients with ILD had significantly higher odds of mortality (OR 1.84, 95% CI 1.02, 3.32), though the odds were significantly lower in the South Asian racial group (OR 0.37, 95% CI 0.14, 0.92) compared with Caucasians.

**Conclusion:** Our study is the first of its kind to demonstrate an association between racial groups, clinical profiles, autoantibodies, and the subtypes of IIM. There is heterogeneity in MSA and MAA positivity among racial groups. Importantly, we show that race appears to have a possible role in the predilection for IIM subtypes and ILD.

**INCREASED RISK FOR STROKE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER, RESULTS FROM A LARGE POPULATION-BASED STUDY**

**Keywords:** Rare/orphan diseases, Real-world evidence, Innate immunity

N. Ben-Shabat1, O. Gendelman1, L. Fisher1, U. Shani1, Y. S. Pat1, D. Magonale3, A. Watad1,2, H. Amital1, 1Sheba Medical Center, Internal Medicine B, Ramat-Gan, Israel; 2Leeds Institute of Molecular Medicine, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

**Background:** The association between chronic inflammatory conditions and cardiovascular disease is well established. Considering Familial-Mediterranean Fever (FMF), few studies exist investigating the risk of ischemic heart disease, and none address the risk of stroke.

**Objectives:** To evaluate the incidence and risk for stroke in FMF patients compared to the general population.

**Methods:** A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All FMF patients diagnosed between 2000-2016 were included and matched with control according to age, gender, and place of residence. Follow-up continued until the first diagnosis of stroke or death. The incidence of stroke was compared between the groups using univariate and multivariate models adjusting for cardiovascular risk factors.

**Results:** 9,769 FMF patients and a similar number of controls were followed up for a median period of 12.5 years. The mean age at the beginning of the follow-up was 25.7 years. 208 FMF patients were diagnosed with stroke compared to 148 controls, resulting in an incidence rate (per 10,000 persons-years) of 19.8 (95%CI 17.2-22.7), and 13.9 (95%CI 11.8 to 16.4) respectively, and a crude HR of 1.42 (95% CI 1.15 to 1.76; P<0.001). In a multivariate analysis, FMF patients who developed amyloidosis with related or non-related renal failure demonstrated significant stroke risk (HR=2.16; 95%CI 1.38 to 3.38; P<0.001), as well as for those who did not develop these complications (HR=1.32, 95%CI 1.04 to 1.67; P<0.05).

**Conclusion:** FMF patients are at increased risk for stroke regardless of known complications.

† Including amyloidosis, chronic renal failure, dialysis, and kidney transplant.‡ Adjusted for age, sex, and cardiovascular baseline risk factors.§ Compared to a similar number of matched controls.
CKD as serum creatinine >1.0mg/dl with eGFR <60ml/min/1.73 m2 and micturative urinary sediment, confirmed by at least three determinations for at least 3 months, and damage was measured by the SLICC damage index (SDI). Non-parametric tests were used for comparisons.

**Results:** 303 LN patients were included (females 86.5%, mean follow-up 14.8 (9.8-22.0) years), 257 patients (84.8%) achieved remission after a median of 1.44 (0.69-3.58) years from initial treatment, which persisted throughout follow-up in 115 patients. Among 142 patients who had their remission interrupted, 39 (27.5%) did so due to extrarenal flares, while 103 (72.5%) experienced renal flares (creatinine or proteinuria). Loss of remission due to extrarenal flares was less frequently associated with CKD development than remission lost to renal flares (5.1% vs. 28.2%, respectively; OR95% CI 0.14 (0.031-0.61), p=0.003), while the ultimate median annual SDI increase was comparable between patients experiencing either renal or non-renal flares (renal vs. extrarenal flares: +0.05 (0.01) vs. +0.06 (0.14), p=0.8).

**Conclusion:** Patients experiencing renal flares are at greater risk of CKD, yet more than 5% of patients undergoing extrarenal flares develop CKD. Renal and extrarenal flares both contribute comparably to damage accrual across all organ domains. Extra-renal flares deserve attention and should not be regarded as mild by definition.

Validation of outcome measures and biomarkers

Objectives: (i) To determine whether sample type affects the previously defined IFN score, (ii) to develop revised IFN scores in WB, (iii) to identify the best RG for future RT-PCR experiments.

Methods: Samples were collected from participants enrolled in 5 studies; DEFINITION, CONVAS, USEFUL, MASTERPLANs and BRAGSS. PBMCs were separated from blood using leucosep tubes and WB was collected using Tempus™ Blood RNA Tubes. Undetected delta Ct values were singly imputed. IFN scores A and B were calculated in paired WB and PBMC samples and agreement between the sample types was assessed via the Bland-Altman (BA) method. New IFN scores for WB were derived via exploratory factor analysis (EFA) of 31 ISG as per the original work [1]. Separation of clinical subgroups was visualized using violin plots and effect sizes calculated using Hedges’ g. RG identification from 16 candidates used online software.

Results: We used samples from 342 participants with systemic lupus erythematosus (SLE), 6 ANA positive at risk progressors, 7 at risk non-progressors, 30 with rheumatoid arthritis (RA) and 10 healthy controls (HC). Subsets were used for sample comparison (n=45) and RG work (n=22). Comparing score A in PBMC versus WB matched samples resulted in bias of -1.44, limits of agreement (LOA) 0.08, -2.96, the spread of data on BA plot showed a systematic difference. The same comparison in score B gave bias of -1.23 (LOA 0.26, 2.73), data on BA plot suggested differences were not systematic. EFA in WB produced a two-factor solution which explained 97% of the variation. The first (score C) contained 3 ISG and the second (score D) contained 4 (Table 1), compared with score A (12 ISG) and score B (14 ISG) [1]. Both scores showed potential to differentiate between HC and those with SLE or RA, but neither separated SLE from RA as the original PBMC scores A and B had done (Figure 1). YWHAZ, PGK1 and GUSB were the most stable RG. Others such as ACTB performed poorly as RG.

Conclusion: PBMC and WB may be used interchangeably to calculate IFN score A, but not score B. This suggests an influence of neutrophils, including the demethylation of neutrophil ISG cytokine-gene sites, on Score B genes [3]. In WB we derived a further two scores which differentiated SLE or RA from HC, although neither score distinguished between SLE and RA. Further work is needed to assess the performance of scores A-D in WB samples. The Minimum Information for Publication of Quantitative Real-Time PCR Experiments recommends using ≥3 RG to avoid bias [4]; we found that YWHAZ, PGK1 and GUSB were the most stable genes across a range of experimental conditions.

reported grip-difficulties, and 14% incomplete fist-closure: all were associated with tenosynovitis. Decreased dynamometer-measured grip strength was most sensitive for detecting tenosynovitis (75%), while incomplete fist-closure was most specific (88-90%).

**Conclusion:** Hand function is already often affected before RA-development, reflecting subclinical inflammation. In practice, testing hand-function in CSA-patients could conveniently objectify functional limitations and reveal subclinical tenosynovitis.

**REFERENCE:**

**Figure 1.** Assessment and prevalence of reduced hand function in the CSA-phase. Legend: Figure 1A depicts the different measures of hand function used: I Dynamometer-measured grip strength (GS), II patient-reported grip-difficulties in the HAQ grip-domain, III fist-closure, IV Examiner-assessed. In B, dynamometer-measured grip strength was compared to the mean grip strength in healthy individuals of the same age and sex as reported by Günther et al.(1) Patient-reported grip-difficulties were defined as a score of 1 or higher (i.e. individuals indicating some difficulty, much difficulty or unable to perform a task) in the HAQ grip domain. I, III and IV were assessed in the derivation-cohort, II, III and IV in the validation-cohort. GS: grip strength.

EXPLORING SMARTPHONE-BASED DIGITAL ENDPOINTS FOR RHEUMATIC CONDITIONS

Keywords: Outcome measures, Telemedicine, Validation

R. Araújo1, P. Matias1, P. Studenti3, M. Valada1, R. Graça1, N. Nakhost Lotfi2, D. Belo1, F. Nunes1,1, Frauenhofer Portugal AICOS, Research Center for Assistive Information and Communication Solutions, Porto, Portugal; 2Medical University of Vienna, Internal Medicine 3, Division of Rheumatology, Wien, Austria; 3Karolinska Institute, Medicine (Söna), Division of Rheumatology, Stockholm, Sweden; 4Nova Medical School, EpiDoc Unit, CHCR, Lisbon, Portugal

Background: The care of rheumatic diseases is currently episodic, based on visits every 3-6 months at the rheumatologist, which may fail to characterize the condition state. To address this issue, the research community is investigating ways to use smartphones and sensors to monitor conditions passively.

Objectives: Explore associations between smartphone-generated data, standardized functional tests, and Patient Reported Outcome Measures (PROMS) to support the creation of digital endpoints.

Methods: Participants from Portugal and Austria participated in a Data Collection that included: (i) physical activities, such as walking with a smartphone in the pocket; (ii) hand dexterity exercises, such as copying text sentences with the smartphone keyboard; (iii) downloading and processing sociability data from the participants’ smartphones; (iv) performing functional tests, such as Moberg Pick-Up Test (Moberg) and Timed Up-and-Go (TUG); and (v) answering validated PROMS, such as MD-HAQ, EQ-5D-5L, and visual analogue scale (VAS) for pain, fatigue, and disease activity. Statistical analysis focused on the correlation between smartphone-collected data and functional tests or PROMs, and independent t-test for between-group comparison.

Results: We collected data from 59 participants (76% female, 24% male). From this set, 31 were patients diagnosed with osteoarthritis (45%), rheumatoid arthritis (26%), or psoriatic arthritis (29%). The remaining 28 were age-matched healthy controls. In terms of age, 17% of participants were under 41 years old, 52% were between 41 and 60, and 31% were 61 or older. Most patients reported stiffness or pain in the upper (90%) and lower (83%) parts of the body. Subjective health status was high (M=7.97, SD=16.31) in the VAS of EQ-5D-5L. Independent t-tests (Table 1) showed significant differences between patient and control groups regarding Mobility (M= 1.90, SD= 0.77), Pain/Well-Being (M= 2.48, SD= 0.81), and Mental Health (M= 1.68, SD=0.83) with higher difficulty levels reported by rheumatic patients compared to controls. Rheumatic patients also rated worse in HADS anxiety (M= 5.90, SD= 3.74) but not depression. We found significant differences between patients and controls in the variability of key pressing time (ms), with less variability among patients than controls (M= 30.71, SD= 11.99). The inter-key typing time was lower in participants below 50 years than above. A moderate correlation was found between patient and control groups regarding Mobility (r= -0.92, p <.001), as well as the standing up (r= 0.59, p = 0.02) and the number of total steps (r=0.81, p= 0.035) in patients with hand joint pain. Regarding Mobility associations, TUG found between the number of character deletions and the Moberg test (r= 0.44, p <0.001 -0.72 1 .26±0.364 0.98±0.24

Conclusion: Data collection with smartphone appears to have face, construct and discriminative validity, able to support future trials in patients with rheumatic diseases, to validate smartphone-based data vs objective measures of disease activity and quality of life over time.

POSO079

THE GLUCOCORTICOID TOXICITY INDEX-METABOLIC DOMAINS: AN ABRIDGED VERSION OF THE GLUCOCORTICOID TOXICITY INDEX

Keywords: Outcome measures

N. Patel1, D. Jayne2, P. A. Merkel3, P. Bekker1, Y. Zhang1, M. Stone3, H. Yue1, H. Stone1, 1Massachusetts General Hospital, Rheumatology Unit, Boston, United States of America; 2University of Cambridge, Medicine, Cambridge, Cambridgeshire, United Kingdom; 3Hospital of the University of Pennsylvania, Rheumatology Unit, Philadelphia, United States of America; 4ChemoCentryx, Inc., Clinical Development, San Carlos, United States of America; 5Steritas, LLC, Clinical Outcomes Assessments, Concord, United States of America; 6Amgen, Inc, Clinical Development, Thousand Oaks, United States of America

Background: Measurement of glucocorticoid (GC) toxicity is critical to efforts to reduce it. In clinical trials, the Glucocorticoid Toxicity Index (GTI)[1] measures toxicity effectively using two scores, the Cumulative Worsening Score (CWS) and the Aggregate Improvement Score (AIS). In clinical practice, high patient volumes limit time available to perform the full GTI. An abbreviated GTI version – the GTI-Metabolic Domains (GTI-MD) – may address this issue by including only data that are collected routinely at clinic visits, requiring no additional physician time. The GTI-MD includes four domains: Body Mass Index, Glucose Tolerance, Blood Pressure, and Lipid Metabolism.

Objectives: We evaluated the correlations between the GTI-MD, overall GTI scores, and the remaining GTI domains to determine if the GTI-MD differentiates patients effectively according to GC toxicity.

Methods: We used data from ADVOCATE[2], a phase 3 trial in which avacopan replaced a standard GC taper in ANCA-associated vasculitis, to test the correlation of the GTI-MD with overall GTI scores. We evaluated the ability of the GTI-MD to differentiate the treatment groups by GC toxicity, comparing GTI-MD scores between groups at weeks 13 and 26.

Results: The abilities of the full GTI domains to differentiate the treatment groups according to GC toxicity have been reported[3]. The Spearman rank correlation coefficient for the GTI-MD CWS with GTI CWS was 0.78 (p <0.0001). The corresponding correlation for the AIS was 0.73 (p <0.0001). The GTI-MD distinguished the two groups by GC toxicity at both 13 and 26 weeks (Table 1). The mean GTI-MD CWS was lower in the avacopan group, consistent with less toxicity (15.9 versus 23.0 at 13 weeks [p=0.001]; 26.7 versus 31.7 at 26 weeks [p=0.009]). The GTI-MD AIS values were also consistent with less toxicity in the avacopan group (2.5 versus 13.0 at 13 weeks [p=0.0003], 4.4 versus 10.1 at 26 weeks [p=0.03]). Contributions of the four GTI-MD domains were balanced (Figure 1). A GTI-MD score of zero correlated with low toxicity in other domains.

Conclusion: We used data from ADVOCATE[2], a phase 3 trial in which avacopan replaced a standard GC taper in ANCA-associated vasculitis, to test the correlation of the GTI-MD with overall GTI scores. We evaluated the ability of the GTI-MD to differentiate the treatment groups by GC toxicity, comparing GTI-MD scores between groups at weeks 13 and 26.

GTI-MD Score Week Treatment Group Mean Score Standard Deviation P-value

AIS 13 Avacopan 160 2.5 23.4 0.0003

Prednisone 161 13.0 27.3

26 Avacopan 154 4.4 25.7 0.03

Prednisone 153 10.1 26.1

CWS 13 Avacopan 160 15.9 15.7 0.001

Prednisone 151 23.0 19.2

26 Avacopan 154 28.7 20.1 0.009

Prednisone 153 31.7 20.3

Table 1. – Group comparison through independent t-test applied to some of the collected variables.

Table 1. – Group comparison through independent t-test applied to some of the collected variables.

Table 1. Differentiation of the two treatment groups in ADVOCATE by glucocorticoid toxicity, as measured by the Glucocorticoid Toxicity Index-Metabolic Domains.
Conclusion: The GTI-MD correlated well with the full GTI in ADVOCATE and may be incorporated readily into routine clinic workflows. Additional studies will be required to determine how effectively the GTI-MD predicts certain long-term GC toxicities such as osteonecrosis, bone fractures, infection, and death, and to understand how the instrument performs in other types of settings and study designs. Utilization of the GTI-MD may help clinicians monitor GC toxicity longitudinally, with the goals of preventing the burden of chronic, treatment-related morbidity, and reducing long-term costs to health systems.

Keywords: Outcome measures, Validation, Rheumatoid arthritis

V. Konetzke1, A. Kerschbaumer1, J. S. Smolen1, D. Aletaha1, Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria

Background: An accurate evaluation of efficacy is key in any trial of novel pharmaceutical compounds. For rheumatoid arthritis (RA), the American College of Rheumatology 20, 50 and 70 response criteria (ACR20/50/70) were reported in all major clinical trials since 1995. Although clinically irrelevant, the ACR20 response still remains the primary endpoint required by the European Medicines Agency (EMA) and the US Food and Drug Administration (FDA).

Objectives: In this analysis we explored how the stringency of the ACR response definitions (20%, 50% or 70%) differs with respect to their observed frequency and timing to inform potential future trial designs and regulatory decisions on required claims during the drug approval process in RA.

Methods: We conducted a systematic literature search in EMBASE, Medline and the Cochrane Library for multi-national, multi-center, phase 3 randomized drug trials (RCTs) investigating biological and targeted synthetic disease modifying anti-rheumatic drugs (bDMARDs/tsDMARDs) in adult RA patients. We included full articles published in English and reporting ACR responses for ≥3 time points over a 24-week study period. Baseline characteristics as well as ACR responses were extracted. For direct comparison of the response dynamics over time, we visualized ACR response rates on scales normalized to their maximum numerical responses observed during the respective trial (for details see legend). Calculation of p-values per outcome and timepoint for each treatment arm against placebo (Fisher’s Exact test; α=0.05) allowed us to compare the discriminative capacity of the ACR responses between active treatment and placebo across all timepoints. Statistical analyses were done using R (V4.2.1, 2022, Vienna, Austria).

Results: We screened 12,457 articles (AK and VK) and selected 313 articles for full-text reading; we included 44 articles in the final analysis, which allowed for comparison of 95 treatment arms against placebo, investigating 8 different modes of action in DMARD-naïve patients as well as csDMARD and bDMARD insufficient responders (IR). The discriminative capacity of the ACR20 was highest across all timepoints analyzed (week 1 to 24), on average reaching 70% of the maximum response rate in the trial as early as by week 2 (normalized ACR response, Figure 1, Panel A). In contrast, ACR50 and 70 responses reached rates comparable to the ACR20 close to or at week 24, thus exhibiting slower response dynamics (Figure 1).

Figure 1. Mean normalized ACR responses. ACR responses were normalized to the respective maximum response achieved during the course of the trial; for example, if the maximum ACR20 response rate was observed at week 16 and amounted to 76% responders, then this was the normative 100% in the respective trial; and if the maximum ACR70 response rate was observed at week 20 and amounted to 28%, then this was taken as 100% for the ACR70 response. These data are summarized in panel A for DMARD naïve patients (n=12), csDMARDs IR (n=74) and bDMARD IR (n=95) (number of treatment arms); Panel B: Percentage of treatment arms (n=95) from 44 different trials with significant (p≤0.05) ACR20, 50 and 70 response (active treatment vs. placebo) per timepoint (week 0-24).

Figure 1. Percentage of the Glucocorticoid Toxicity Index-Metabolic Domains score contributed by each domain at 13 and 26 weeks, as reflected by the Aggregate Improvement Score values adjusted for weight.
Panel B). This effect was seen across all treatment arms (N=95) and independent of the mode of action, but slower for trials including treatment-IR patients compared with those assessing DMARD-naive patients (Figure 1, Panel A).

**Conclusion:** The ACR20 response definition continues to be the most powerful discriminator between active treatment and placebo at early timepoints during trials; however, the discriminative capacity of the ACR50 and 70 definitions increases over the course of time. Our findings therefore support the use of these clinically more relevant response definitions at later but not early timepoints.

### POS0981

**PRECISION MEDICINE IN RHEUMATOID ARTHRITIS. EVALUATION OF TWO NOVEL TESTS TO PREDICT CLINICAL RESPONSE TO METHOTREXATE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

**Keywords:** Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Biomarkers

A. Escudero Contreras1, F. J. Blanco2, M. Alperi-López3, A. I. Turnión4, C. Lopez-Pedreña5, T. Yebra6, G. Cordero7, T. Diez8, I. Portero9; 1Hospital Reina Sofia de Córdoba, Rheumatology, Córdoba, Spain; 2Complejo Hospitalario Universitario de A Coruña (CHUAC), Rheumatology, La Coruña, Spain; 3Hospital Central de Asturias, Rheumatology, Oviedo, Spain; 4Hospital Universitario de Salamanca, Rheumatology, Salamanca, Spain; 5Biohope Scientific Solutions for Human Health, Medical, Ires Cantos, Madrid, Spain

**Background:** The main goal of treatment in patients with early Rheumatoid Arthritis (RA) is to achieve a clinical remission. Methotrexate (MTX) should be the first treatment strategy in naive patients, but about one third will not respond to this therapy. There is a lack of tools to predict the individual response to MTX. Pre-treatment number of circulating monocytes may predict clinical response to MTX (1) and ROS production may be related to the pharmacological action of MTX (2, 3). The main goal of our research was to test the hypothesis that ROS production may be related to the pharmacological action of MTX (2, 3).

**Objectives:** To evaluate the feasibility of 2 novel tests (ROS and Monocytes Tests) to measure in vitro the sensitivity to MTX in patients with new-onset RA and the association of MTX response with clinical remission at 6 months.

**Methods:** This is an observational, longitudinal Proof-of-Concept with a follow-up of 6 months. 33 adult patients with early RA according EULAR criteria and with a baseline a patient blood sample was collected, where PBMCs were isolated and frozen. After 3 weeks, PBMCS were defrost, placed in a plate p96, activated with phytohemagglutinin, and exposed to MTX. In the ROS test, Reactive Oxygen Species levels as determined with the ROS test showed to be increased in patients with clinical remission vs patients without remission (p<0.001) (Figure 1). The predictive capacity of these models was analyzed with the area under the operating characteristics curve (ROC), showing for ROS Test an AUC of 0.919 (CI95% 0.813-0.989) (p<0.0001) and for Monocytes test 0.826 (CI95% 0.664-0.989) (p<0.0001).

### Clinical cases

### POS0982

**UNUSUAL PRESENTATION OF LEWIS-SUMNER SYNDROME IN ELDERLY SIMULATING POLYMYSITIS AND POLYMIALGIA RHEUMATICA**

**Keywords:** Rare/orphan diseases

M. Brahem1, R. Sarraj1, O. Jomaas1, B. Jebali1, S. Abdellatif1, H. Hachfi1, Y. Mohamed1; 1Taher Star University Hospital, Rheumatology, Mahdia, Tunisia

**Background:** Lewis-Sumner syndrome (LSS) or multifocal acquired demyelinating sensory and motor neuropathy (MADSAM) is an atypical form of chronic inflammatory demyelinating polyneuropathy (CIDP). This rare disease is characterized by a predominantly distal, asymmetric weakness mostly affecting the upper limbs and motor dysfunction with adult onset. Diagnosis can be difficult to establish if the clinical presentation is atypical and frequently simulates inflammatory myopathy.

**Objectives:** Methods: We report a rare case of LSS in an old patient with unusual clinical aspects.

**Results:** A 70-year-old female patient with a history of atrial fibrillation complicated by pulmonary embolism, presented with myalgia and muscle weakness of the shoulders, upper arms, hips and thighs. This involvement was bilateral, symmetric and evolving since 3 months, causing difficulties in climbing stairs, standing or walking. Physical examination showed a proximal muscle deficiency affecting proximal muscles of the upper and lower limbs. In this stage we suspected a poly myositis or polymyalgia rheumatica. We completed by biological assessment that showed a biological inflammatory syndrome (ESR at 90 mm at first hour; CRP at 80mg/L) and elevated lactate dehydrogenase level at 490 IUL. The immunoblot polymyositis profile (anti-M2, anti-Ku, anti Pm/Scl, anti-Jo, anti-PL12, anti-P17, anti-SSA 52kDa, anti-EJ, anti-OJ and anti-SRP) was negative. The MRI of lower limbs revealed a signal abnormality in the gluteus medius muscles on both sides with inflammatory appearance. The Electromyography revealed sensorimotor neuropathy affecting the four extremities with motor nerve conduction blocks. This aspect was in favor of LSS, so we completed by a cerebrospinal fluid study which revealed a proteinorachia at 0.4g/l with normal glycorachia and normal cell counts. These results confirmed the diagnosis of LSS. The patient was treated by corticosteroids at dose of 1 mg/kg/day during 2 months, with a progressive decrease of treatment. The evolution was marked by a spectacular clinical and biological response.

**Conclusion:** LSS is a very rare disease that can simulate inflammatory myopathy and polymyalgia rheumatica in elderly. So, it should be suspected in old patients suffered from proximal muscle deficiency.

### POS0983

**TET2 MOSAICISM IN HUMAN IS ASSOCIATED WITH A COMPLEX PHENOTYPE INCLUDING LYMHPHOPROLIFERATION, AUTOIMMUNITY, IMMUNODEFICIENCY, AND HEMATOLOGIC MALIGNANCY**

**Keywords:** Autoantibodies, Genetics/epigenetics, Malignancy

R. Lorenzet1, J. Staniek1, M. Rizzi1, R. Völl1, N. Venhoff1, J. Thiel1,2; 1Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Faculty of Medicine, Albert-Ludwigs-University of Freiburg,
Background: The TET2 gene encodes ten-eleven translocation methylcytosine dioxygenase 2 (TET2). TET2 is an epigenetic regulator that converts 5-methylcytosine to 5-hydroxymethylcytosine and also interacts with histone-modifying enzymes and transcription factors. Somatic mutations in TET2 are early events in clonal expansion and are found in association with myeloid and lymphoid hematological diseases. Germline mutations in TET2 have only been described in 3 children of consanguineous parents. These mutations led to immunodeficiency and lymphoma and early mortality in childhood.

Objectives: To assess the clinical and immunological consequences of a combination of a germline and a somatic mutation in TET2.

Methods: Genetic analysis was done by whole exome sequencing. An in-depth immunological analysis was performed.

Results: Clinical phenotype: The patient of non-consanguineous parents presented at the age of 38 with axial spondyloarthritis. Apart from trace homogenous fluorescence on the HeP2 cell his immunologic work-up was unremarkable. After start of a TNF-inhibitor he developed persistent fever, serositis, interstitial lung disease, peripheral arthritis and a pronounced lymphadenopathy/pleural-nemegaly. His condition improved after the TNF-inhibitor was changed to an IL-17-inhibitor combined with prednisone (up to 40mg/d), but lymphadenopathy persisted and the patient recurrently suffered from fevers, fatigue and pleurisy. Lymphnode biopsies showed no signs of malignancy. The patient had recurrent episodes of pancytopenia that spontaneously improved and he developed two episodes of pneumonia. Furthermore, he suffered from recurrent episodes of herpes zoster. Immunological results: On immunologic work-up the patient had a polyclonal hypergammaglobulinemia and autoantibody testing revealed a homogenous ANA (1:1600), and positive anti-nucleosome-, anti-PM-Scl70-, anti-SRP-, anti-PL-12-, anti-phospholipid-, anti-dsDNA- and anti-MPO-autoantibodies.

Despite of increased amounts of immunoglobulins the patient developed a progressive and persistent loss of B cells (Figure 1), with an increased expression of CD80/86 on the remaining memory B cells. Within the T cell compartment double-negative T cells were increased.

Results of whole exome sequencing: Whole exome sequencing revealed a germline mutation in TET2 with the variant c.3641G>A; p.Arg1214Gln in the heterozygous state (NAF 0.53; NM_001127208.3). This mutation affects a phylogenetically conserved amino acid and is classified as predominantly pathogenic in the in silico prediction. Another variant identified is the mutation c.1864C>T; p.Gln622, which leads to the emergence of a stop codon (NAF 0.041). This variant was only detectable as a low-grade mosaic (5-10%) in the buccal mucosa in the control, possibly as a result of lymphocytic infiltration into the buccal mucosa. In leukocytes, this mutation was detectable in 83% of cells in the heterozygous state. Both mutations have a low frequency in the population (1-2/120000-150000; gnomAD).

Hematological malignancy: 5 years after the progressive loss of B cells started, the patient was diagnosed with a follicular B cell lymphoma and shortly after with AML with myelodysplasia-associated changes (AML-MRC). A familial-allogeneic peripheral blood stem cell transplantation was performed. During the now 6 months follow-up no relapse occurred.

Conclusion: Combined heterozygous germline and somatic mutations in TET2 are associated with a very complex phenotype combining autoimmunity, lymphoproliferation and hematological malignancy, may present in adulthood and thus clinically differ from combined heterozygous germline mutations with early onset in childhood.

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease that can have a major impact on patients' quality of life with functional and psychological impairment.

**Objectives:** To investigate the impact on patients' quality of life and the effectiveness of a digital social media campaign to provide education and awareness about PsA.

**Methods:** A cross-sectional study was conducted involving patients with PsA, according to the CASPAR criteria. Sociodemographic data, clinical, and therapeutic modalities were collected. Patients were asked to respond to the Experience of Shame Scale (ESS) [1] and to the Test of Self Conscious Affect- Version 3 (TOSCA-3S) [2].

**Results:** The mean Psoriatic area severity index (PASI) was 10.2 [0–70]. For the ESS, the mean total score was 63 [31–98] with a mean subscale score of: 28 [14–45] for characterological shame, 25 [12–35] for behavioral shame and 9 [5–20] for bodily shame. For the TOSCA-3S, the mean “shame self-talk Total” score was 33 [17–44], and the mean “guilt self-talk Total” score was 47 [37–55]. A significant positive correlation was noted between the PASI and the bodily shame score (p<0.001, r=0.673). A significant positive correlation was noted with the educational level (p=0.027). The Bodily shame subscale was associated with educational level (p<0.027). The Bodily shame subscale was associated with the educational level (p=0.028). A significant positive correlation was noted between the PASI and the bodily shame score (p=0.001, r=0.673).

**Conclusion:** Feelings of guilt and shame were frequent among PsA patients. Associated factors were mainly disease activity, PASI, and sociodemographic parameters.

### Best practice campaigning

POS0986-PARE

**IMPACT OF EDUCATIONAL CAMPAIGNS ON RMD IN SOCIAL NETWORKS**

**Keywords:** Education, Self-management, Quality of life

E. Pinzon1, L. Higueras2,1, FUNARP, Education, Panama, Panama;1,2 FUNARP, Education, Panama, Panama

**Background:** Panama’s prevalence of rheumatoid arthritis lies within the global range (2.4 to 1%). To improve the quality of life of RMD patients in the country, FUNARP was created over 18 years ago to educate and support patients, caregivers, and civil. FUNARP decided to focus its efforts on digital campaigns since 2020 taking advantage of its coverage, low costs, and ease of usage. Further, the mobile penetration of Panama is 136% of its population [1] making social media the best distribution channel for this purpose.

**Objectives:** To expand educational coverage, especially for those with limited mobility or living in hard-to-reach areas. Another objective is to measure the effectiveness of digital media campaigns (paid or organic growth), as well as to identify the most effective social network for these purposes.

**Methods:** Social media campaigns complement FUNARP’s annual education plan, which consists of monthly onsite and virtual lectures/seminars. The educational approach is based on the physician’s perspective and the patient’s experience. The campaigns consist of a mixed scheme: selected ad investment and in-house content creation; and full-fledged campaigns with professional content development and paid ads. In 2022, a total of five campaigns were launched following this process: a) selection of the campaign theme, b) professional advice on content; c) sponsorship, d) hiring of the marketing agency, e) approval of design and publications, and f) analysis of results to the board of directors and sponsors.

**Results:** “Early Diagnosis and Motivation to Consult a Rheumatology Specialist” was the most successful campaign - developed by a marketing agency with videos supporting the message, and paid ads on both Instagram and Facebook, see Figure 1. Salient results: 110,486 accounts reached and 25,975 interactions, see Table 1.

**Figure 1.** Best performing campaign. Campaigns with professional content creation and paid ads in social media ads had more than 50% reach and 90% interaction than the ones without them. Videos have a higher acceptance vs. static images, see Table 1.

**Table 1.** Salient KPI of social media campaigns in 2022 (reach vs. engagement)

Qualitative results have been observed by rheumatologists who have indicated that patients who have had access to information from our foundation are more informed and involved in their treatment. They perceive that these patients have a better quality of life compared to those who do not have access to information about their pathology.

**Conclusion:** Working with marketing companies, and rheumatologists, as well as investing in advertising directly influences the effectiveness of health awareness and literacy campaigns. Publications where real patients appear as protagonists had higher acceptance vs. those with stack images and videos, or models. Instagram appears to have a better impact than Facebook. The early diagnosis campaign managed to overcrowd first-time consultations with rheumatologists in the public health system (less than 20 rheumatologists for a 4.2 MM population in Panama). FUNARP observed an increase in requests for information and orientation in the navigability of the system to obtain care with rheumatologists and advice on various health issues from the community through social media messaging services.
HPR Measuring health (development and measurement properties of PROs, tests, devices)

Keywords: Patient reported outcomes, Systemic sclerosis

M. N. Carstens1, T. Garen1, H. Didriksen2, H. Fretheim1, I. Barua1, I. L. Knutsen2, T. Karaslan1, T. Hatteveit1, M. E. Pesonen2, Ø. Midtværd1, Ø. Molberg1, A. M. Hoffmann-Vold1, 3, 4. Oslo universitetssykehus HF, Rikshospitalet, Department of Rheumatology, Oslo, Norway; 5. University Hospital of North Norway HF, Department of Rheumatology, Tromsø, Norway; 6. St. Olav’s University Hospital, Department of Rheumatology, Trondheim, Norway; 7. Haukeland University Hospital, Department of Rheumatology, Bergen, Norway; 8. Domus Medica, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway; 9. University Hospital of Zurich, Department of Rheumatology, Zurich, Switzerland

Background: Systemic sclerosis (SSc) is a multi-organ disease and patient-reported outcome measures (PROMs) are important to better understand the complexity and impact of the disease. This heterogeneous disease has a wide specter of symptoms, and there are several different PROMs in use for this disease-group to assess all possible symptoms. Recently, a SSc-specific patient-devised questionnaire The Systemic Sclerosis Impact of Disease (Scleroid) has been developed and validated. Longitudinally, the questionnaire performed better than other comparators with regard to change over time. The Scleroid has so far not been used in a clinical study, nor been compared with the Scleroderma Clinical Trials Consortium Gastrointestinal Scale (UCLA GIT score).

Objectives:
1. To estimate the sensitivity to change in Scleroid with the UCLA GIT score as comparator.
2. To assess association between upper and lower GI in Scleroid and the UCLA GIT score.

Methods: We assessed the Scleroid and the UCLA GIT score in a 20 weeks randomized clinical trial, including patients with predominantly lower GI symptoms without severe cardiopulmonary complications. The Scleroid includes questions about the severity of Raynaud’s phenomenon, hand function, upper and lower GI symptoms, life style and mobility. It is scored using a 10 points Likert scale, with scores ranging from 0 (no impairment) to 10 (extreme impairment). The UCLA GIT score is a seven-item scale asking for frequency of experienced reflux, distention/bloating, diarrhea, fecal soiling, constipation, emotional well-being and social functioning, where all scales are scored from 0 to 10.

Results: The study cohort included 67 SSc patients with mean age of 61 years and mean disease duration of 10 years (table 1). After week 20, the Scleroid and UCLA GIT total score showed low sensitivity to change, with Scleroid 0.42 (95% CI 0.10, 0.68) and 0.45 (95% CI 0.18, 0.77), respectively (Figure 1). Upper GI score of the Scleroid showed a strong correlation with UCLA reflux (r=0.799, p<0.001), Lower GI of the Scleroid correlated moderately with UCLA reflux (r=0.399, p=0.008), constipation (r=0.306, p=0.031) and distention/bloating (r=0.444, p<0.001). In total, 54% of the patients reported an improvement in upper GI symptoms and 51% in lower GI symptoms of Scleroid. For the UCLA GIT score 56% reported improvement in reflux, 59% in bloating/diarrhoea and 33% in diarrhoea.

Conclusion: The Scleroid and UCLA GIT score showed a low sensitivity to change after 20 week in a lower GI predominant SSc-cohort without severe organ involvement. The majority of the patients reported improvement in upper and lower GI symptoms in both questionnaires.

Background: Methotrexate (MTX) is the cornerstone therapy for rheumatoid arthritis (RA) patients, with well-established safety and efficacy profiles and support in international guidelines. Guidelines state that the maximal effect of MTX in a dose around 25 mg/week can be seen after 3-6 months of therapy. However, older studies showed that the maximum dosage usually is up to 15 mg/week and <40% had started treatment with MTX within 3-6 months from the diagnosis.[1,2,3] Santeon hospitals showed by analysis that disease activity score (DAS 28 CRP) of newly diagnosed RA patients was comparable after 6 months of treatment. Moreover, a large group of new RA patients did not start with MTX, within 3 months but with other csDMARD like HCQ. Our findings rise the urgency of an international induction protocol since the DAS28 did not vary after 3 and 6 months. Moreover this raises the urgency for precision treatment based on patients’ characteristics (gender, rheumafoator, anti CCP) can achieve similar outcomes (low disease activity) using a lower dose of MTX. To identify these characteristics is topic for further analysis.

Results: 28 patients were included in Group 1, 26 in Group 2, and 37 in Group 3. 100% were women. 51.6% showed erosive arthritis, 81.3% of patients had at least one positive test result for rheumatoid factor, and 79.1% had anticitrulline antibodies. 46.2% had secondary level studies. 3. 100% were women. 51.6% presented erosivity, 81.3% positivity for rheumatoid factor, and 79.1% for anti-citrulline antibodies. 46.2% had secondary level studies.

Results: A total of 187 patients were included (median age 54 years; 140 males) with a median DAS-28 of 2.616. Out of 187 RA patients, 103 (55.1%) had lower MedDiet scores (MedDiet ≤ 5). Based on the logistic regression function, we found that the multivariable-adjusted odds ratio of RA patients with high adherence to the MedDiet (MedDiet > 6) had lower DAS-28 scores (OR 5.34, 95% CI 1.176 - 24.230, P-value = 0.030) and improved lipid profiles compared to patients with low adherence.

Conclusion: Higher adherence to the MedDiet among Kuwaiti adults with RA may lead to improved DAS-28 scores. Lifestyle and dietary manipulations may be one of the non-pharmacological methods to control RA activity scores.

Gemelli IRCCS, Roma, Italy

Background: Patients with RA experience a decline in health-related quality of life, which is associated with increased illness severity and impairment of work abilities. Central sensitization (CS) emerges as an accurate predictor and correlate of poor pain experience.

Objectives: The purpose of this cross-sectional, multicentric study is to investigate the mediating role of CS in unfavorable relationships with disease activity levels, CS and work productivity loss due to presenteeism in women with RA, with the goal of identifying potential new targets for preventive interventions.

Methods: The study used a cross-sectional design and included 101 female workers with RA classified according to 2010American College of Rheumatology (ACR)/European League Against Rheumatisms (EULAR) classification criteria. All patients filled out the Italian version of the RAID, an assessment and evaluation tool that measures RA patient disease activity, progress, and outcomes. The Central sensitization inventory (CSI) was used to measure CS, and the Work Productivity and Activity Impairment questionnaire-RA (WPAI-RA) was used to evaluate patients’ employment status. RA patients were grouped into categories, based on their RAID total score. Multiple regression analysis was used to find out which factors were most likely to presenteeism.

Results: The patients’ age ranged from 25 to 65 years, with a disease duration of 5.4 (SD 6.1) years. The CSI score was ≤ 40 in 39/101 patients (38.6%). 70 patients (69.3%) worked full-time, while 31 (30.7%) worked part-time. The

majority of respondents (64.5%) reported a high degree of presenteeism with an average level of 31.8%. On the other hand, absenteeism was uncommon, with just 7.3% of respondents reporting it. Presenteeism was associated with higher CSI score (0.049), increased disease activity (0.0007), disease duration (0.0072) and age (0.0019) (Table 1).

Conclusion: CS disease activity and age were the factor most significantly associated with presenteeism-related productivity loss in RA patients. Our findings have implications for health policy and emphasize the significance of identifying high-risk RA patients by monitoring CS as an indicator of presenteeism and severe disease activity.

NAILFOLD VIDEOCAPILLAROSCOPY CHANGES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHROPATHY ON ANTI-TNF-ALPHA THERAPY

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Psoriatic arthritis

Objectives: To assess the changes in capillary morphology in rheumatoid arthritis and psoriatic arthritis patients after anti-TNF-alpha treatment using nailfold videocapillaroscopy. Videocapillaroscopy is an easy and non-invasive method associated with microvascular involvement that can determine the severity and progression of the disease [1]. Videocapillaroscopy could be useful in monitoring the efficacity of the biological treatment and can be a future tool for the analysis of microvascular heart involvement? Rheumatology (Oxford), 2006 Oct;45 Suppl 4:v43-4. doi: 10.1093/rheumatology/kei310. PMID: 16980724.

CONVERGENT VALIDITY OF SIX MINUTE STEPPE TEST TO EVALUATE FUNCTIONAL EXERCISE CAPACITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Physical therapy/physiotherapy, Validation

S. Bayram1, N. G. Tore1, G. P. Palà1, I. Vasi1, A. Tufan2, D. Oskay3, E. Gazi4, C. Uyar5, University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Gazi University, Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey; 3National Human Genome Research Institute, Infectamatur Disease Section, Rockville Pike, United States of America

Background: Exercise capacity is impaired in systemic sclerosis (Ssc) patients due to respiratory and cardiovascular involvements, muscle weakness, arthralgia, and joint contractures. Various tests are employed to assess submaximal and maximal exercise capacity in Ssc. Maximal exercise tests, the gold standard for assessing exercise capacity, are challenging since they require expensive equipment and qualified personnel. The 6-minute walk test (6MWT) is a commonly used submaximal field exercise test to assess functional exercise capacity and is shown to be associated with the prognosis in SSC patients. The 6-minute stepper test (6MST) is a low-cost, space-friendly submaximal field test that has been demonstrated to be valid, reliable, and sensitive in assessing exercise capacity in various diseases.

Objectives: No research hasn't been done on the validity of 6MST in Ssc patients. One that it mimics stair climbing, the 6MST may be more helpful in evaluating lower extremity functions in Ssc. Therefore, the aims of this study were (1) to assess the convergent validity of the 6MST in Ssc; and (2) to compare physiological responses, dyspnea and fatigue perception obtained in 6MST and 6MWT.

Methods: Thirty female patients with Ssc (52.13 ± 11.83 years) were enrolled. Demographic and clinical characteristics were recorded. 6MST was performed twice (6MST-1 and 6MST-2). To eliminate the learning effect and because the hydraulic jacks become more flexible after they have warmed up. The 6MST-2 was performed after a resting time of at least 20 minutes after 6MST-1. The 6MST was carried out three hours after the 6MST-2 to minimize fatigue on outcomes. To test the convergent validity of the 6MST, correlation between the 6MWT and 6MST-2 was assessed. In addition, the association between 6MST and the level of physical activity, dyspnea and fatigue severity in Ssc patients was investigated. International Physical Activity Questionnaire (IPAQ), modified British Medical Research
Council Questionnaire (mMRc) dyspnea scale, Fatigue Severity Scale (FSS) were used to assess physical activity, dyspnea and fatigue severity, respectively. The heart rate (HR), peripheral oxygen saturation (SpO2), blood pressure (BP), modified Borg scale score for dyspnea, general and leg fatigue were recorded before and after 6MWT and 6MST. Changes between their final and initial values (∆) for HR, SpO2, BP, and modified Borg score were calculated.

**Results:** The number of steps in 6MST-2 was significantly higher than 6MST-1 (p<0.001). The number of steps in the 6MST-2 was significantly correlated with the distance walked in the 6MWT (r=0.616, p<0.0001). Additionally, significant correlations were observed between 6MST-2 and mMRc dyspnea scale score (r=0.733, p<0.0001), FSS score (r=0.575, p<0.001), IPAQ score (r=0.330, p<0.05), ∆SpO2, ∆Spo2, ∆general and ∆leg fatigue perception were higher in the 6MST-2 than the 6MWT (p<0.0001). ∆HR and ∆SpO2 were similar in 6MST and 6MWT (p=0.05).

**Conclusion:** The 6MST is a valid test to evaluate functional exercise capacity in SSc patients. The 6MST might be more appropriate for evaluating perceived exertion, functioning, and lower extremity capacity. To assess the exercise capacity in Ssc patients, 6MST can be done with ease in all settings, including primary care to hospital settings with limited space and home-based telehabilitation.

**THE PREVALENCE OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS**

**Keywords:** Epidemiology, Systematic review, Mixed connective tissue disease

A. Al-Bakri1,2, R. Hozayan2, Z. Mustafa1, I. E. Lundberg3,4, H. Jahrami5,6, King Abdullah Medical City (KAMC), Medicine, Manama, Bahrain; College of Medicine and Medical Sciences, Arabian Gulf University (AGU), Kingdom of Bahrain,Internal Medicine, Manama, Bahrain; College of Medicine and Medical Sciences, Arabian Gulf University (AGU), Kingdom of Bahrain, Medicine, Manama, Bahrain, 3Salamanca Medical Complex (SMC), Medicine, Manama, Bahrain; 4Karolinska Institutet, Stockholm, Sweden, Division of Rheumatology, Department of Medicine, Solna, Stockholm, Sweden; 5Karolinska University Hospital, Stockholm, Sweden, Department of Gastro, Dermatology, Rheumatology, Stockholm, Sweden; 6Arabian Gulf University, Internal Medicine, Manama, Bahrain; 7Ministry of Health, Kingdom of Bahrain, Psychiatry, Manama, Bahrain

**Background:** The prevalence and outcome of mixed connective tissue disease-associated pulmonary arterial hypertension (MCTD-PAH) has not been well understood.

**Objectives:** Our aim was to review the current knowledge on the prevalence, severity, and mortality of MCTD-PAH. We also aimed to examine the trend of the prevalence of MCTD-PAH over the years.

**Methods:** PubMed/Medline, Embase, Scopus and Web of Science electronic databases were searched for the published randomized controlled clinical trials (RCTs) and observational/original studies on PAH in patients with MCTD from January 1972 – December 2020.

**Results:** The results were pooled using random-effects meta-analysis based on the DerSimonian and Laird method. A total of 983 patients from eight studies were included in the meta-analysis (K=8, N=983). Pooled prevalence of PAH in MCTD patients was 12.53% [95% CI 8.30%-18.48%] with significant level statistical heterogeneity tau^2=0.30, tau=0.55, I2 83.3%, H=2.13 Q(7)=<1390, P=0.001. There was no association between PAH and female gender or age. The percentage of deaths in MCTD patients due to PAH varied and reached up to 81.8%.

**Conclusion:** This is the first systematic review and meta-analysis investigating the prevalence of PAH in patients with MCTD and it revealed an overall prevalence of PAH in patients with MCTD of 12.53%. Our results showed trends of reduced prevalence of MCTD-PAH over the years, reconfirmed the lower prevalence rate in the recent studies, but revealed increased mortality rate. We also determined the low impact of the age, gender, and interstitial lung disease on MCTD-PAH.

**SLE-DAS AS AN ALTERNATIVE TOOL TO MEASURE ACTIVITY OF SYSTEMIC LUPUS ERYSHEMATOSUS: COMPARISON WITH SLEDAI-2K, IN A POPULATION FROM THE DOMINICAN REPUBLIC. PILOT STUDY**

**Keywords:** Systemic lupus erythematosus

L. Pérez Rodríguez1, R. A. Alvarez Santana1, D. García1, T. Polanco Mora1, L. Concepción Sánchez2, I. Paulino1, I. Merced3, E. Rodríguez Bautista1, T. Valdez1, A. Fier2, R. Muñoz Louis1, Hospital Padre Bilíndi, Rheumatology, Santo Domingo, Dominican Republic

**Background:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that mainly affects women. Efforts are currently being made to validate the Systemic Lupus Erythematosus Disease Activity Score (SLE-DAS), since it allows quantifying the magnitude of the findings as opposed to an arbitrary value of present or absent in the renal, joint, hematological and serological spheres. [2]

**Objectives:** To evaluate the activity of Systemic Lupus Erythematosus with the SLE-DAS tool, comparing it with SLEDAI-2K.

**Methods:** Descriptive, observational, transversal. Patients from the Rheumatology Service of the Padre Bilíndi Teaching Hospital were evaluated between October-December 2022. Inclusion criteria: > 18 years, SLE according to the EULAR/ ACR 2019 classification criteria. Exclusion criteria: diagnosis of another autoimmune disease, patients with cognitive deficits. SLE-DAS tool: Inactive ≤2.08, mild 2.08-7.64, moderate/severe >7.64, SLEDAI: Inactive: <3, Mild to moderate: 3/12, severe >12. Descriptive analysis and Spearman’s rho (μ) correlation using SPSSv23.

**Results:** 92 patients met inclusion criteria. 95.7% (88) female, mean age 41.5 ± 12 years, mean SLE 8.2 years. AHT 29.3% (27), DM 7.6% (7), lupus nephritis 35.6% (33), Obesity 76.7% [7], musculoskeletal 20.6% (19), Vasculitis 6.5% [6], Neuro Lupus 4.3% [4], antimalerials 98.7% (89), glucocorticoids 39.1% (36), Mycophenolate Mofetil 40.2% (37), Rituximab 76.7% [7], Methotrexate 5.4% [5], Azathioprine 4.3% [4], Tacrolimus 2.1% (2), Cyclosporinamide 1.1% [1]. SLE- DAS inactive: 81.5% (75) vs SLEDAI inactive: 88% (81), SLE-DAS inactive: 81.5% (75) vs SLEDAI inactive: 88% (81) (Spearman’s rho (μ) = -0.11), a gradient difference of 6.5% [6].

**Conclusion:** Our study demonstrated a significant inverse correlation in the correlation between SLE-DAS vs. SLEDAI in inactive patients, supporting that the use of the SLE-DAS may be more sensitive to assess activity or changes in the clinical course of patients with SLE. More studies are needed to validate this tool and standardize it for our population.

Protection Agency (EPA) to represent environmental quality to better understand the association between environmental factors and lupus deaths. Five domains including air, water, land, built and sociodemographic comprised the EQI.

Objectives: Here, we summarize the descriptive statistics between environmental exposures and lupus death and compared them to accidental deaths, heart disease and malignant neoplasm.

Methods: The study population comprises all individual U.S. deaths from 2006 to 2011. We describe mean/median EQI in lupus deaths versus those who died of other leading causes of death, namely accident, heart disease, and malignant neoplasm. Cause-specific death counts were obtained using ICD 10 codes: lupus (M312, M328, M329), accident (V.W, X0-5, Y85-86), heart disease (I0, I11, I13, 12-14, I50-51), and malignant neoplasm (C0-8, C90-97).

Results: There were 5,430 lupus deaths and 398,382 accidental deaths in the US from 2006 to 2011. The total EQI was significantly worse in lupus decedents than in accidental deaths (p<0.001), but not when compared to deaths attributed to heart disease and malignant neoplasm. Of the five EQI domains, air and built, but not the other three domains, were higher in lupus decedents than in accidental (p<0.001), heart disease (p<0.05), and malignant neoplasm (p<0.05) decedents.

Conclusion: Total environmental quality as well as its air and built domains were worse in lupus decedents than in accidental deaths, suggesting a possible role of environmental exposure in contributing to lupus outcome. Further analysis is needed to identify the specific environmental determinants, which are potentially modifiable to improve lupus outcome.

Figure 1. Distribution by gender of patients residing in Piedmont with exemption for Sjogren's Syndrome. F: Female; M: Male

Conclusion: This research has some limitations, including the retrospective design and the use of administrative data which may be affected by the aforementioned difficulty of classification as well as incorrect attributions of exemption, both for SSj and for associated pathologies. Our research highlights a number of patients with primary SSj lower than the prevalence figure that defines a rare disease, i.e. a prevalence of less than 5 cases per 10,000 inhabitants. Further studies are needed to confirm these preliminary data.

Keywords: Rheumatoid arthritis, Epidemiology, COVID
Methods: Data from the Clinical Practice Research Datalink Aurum were analysed from 01/04/17 to 01/10/2021 to describe episodes of care for patients with musculoskeletal (MSK) conditions, in a primary care setting, for pre-COVID-19 (01/04/2017–30/03/2020), early-COVID-19 (01/04/2020–31/07/2021), and late-COVID-19 pandemic (01/08/2020–31/10/2021) periods. Prevalent and incident MSK consultations were determined. Referrals were matched to these consultations. Trends in referrals to MSK services and further incident diagnoses of iRMDs were described using Joinpoint regression and comparisons made between time-periods. Negative binomial regression was used to compare incident rates between time-periods: first MSK consultation to RA/JIA/RMD diagnosis; first MSK consultation to first referral; first referral to RA/JIA/RMD diagnosis. The number of consultations between first MSK consultation and referral/diagnosis were described. Results were adjusted for age and sex and further stratified by geographical region and deprivation.

Results: The incidence of RA and JIA reduced by -13.3% (from 32.0 to 17.2 per 100,000) and -17.4% (from 1.8 to 0.97 per 1,000,000) per month respectively between January 2020 and April 2020, and then increased by 19% (from 17.2 to 25.2 per 100,000) and 3.7% (from 0.97 to 1.3 per 1,000,000) per month respectively between April 2020 and October 2021. The incidence of all diagnosed iRMDs was stable until October 2021. Referral incidence decreased between February 2020 and May 2020 by -16.8% (from 4.8 to 2.4 per 100) per month in patients presenting with a MSK condition. After May 2020, referrals increased significantly (16.8% per month from 2.4 to 4.5 per 100) to July 2020. Time from first MSK consultation to RA diagnosis, and referral to RA diagnosis increased in the early-pandemic period (rate ratio (RR) 1.11, 95% confidence interval (CI) 1.07-1.15; RR 1.23, 95%CI 1.11-1.30) and remained consistently higher in the late-pandemic (RR 1.13, 95%CI 1.11-1.16; RR 1.27, 95%CI 1.23-1.32) periods respectively, compared to the pre-COVID-19 period.

Conclusion: Patients with underlying RA/JIA that developed during the pandemic may delay in seeking healthcare until in the process of being referred and/or diagnosed. Primary care clinicians should remain alert to this possibility and consider the use of fast-track referral pathways where indicated. It is apparent that patients developing incident episodes of inflammatory arthropathies may display a prodrome of symptoms that merits consideration. Referrals to MSK services and further incident diagnoses of iRMDs were described. Results were adjusted for age and sex and further stratified by geographical region and deprivation.

Methods: From a large cohort of 181 APS patients included in a study from 2011-2012, year at University Clinical Hospital Center Bezanjiška kosa, Belgrade, Serbia, data for the occurrence of MACE in 10 years of follow-up were evaluated in 82 patients (86.6% females, 62.1% with primary (PAPS), and 37.8% patients with APS associated with systemic lupus erythematosus (SLE) (sAPS)). At the inclusion in all patients, a transthoracic echocardiography study for the assessment of dimensions and functionality of the left and right heart along with valvular functions and morphology has been performed along with color doppler scan of carotid arteries for the intima-media thickness and presence of plaques, and low- and flow-mediated dilatation of the brachial artery (FMD) as markers of subclinical atherosclerosis. Standard atherosclerotic risk factors prevalence was analyzed. Antiphospholipid antibodies (aPL) analysis included the detection of aCL (IgG/ IgM), IIF (IgG/IgM), and LA, and all patients were treated according to the valid guidelines by the rheumatologist. Data regarding the occurrence of new myocardial infarction (MI), cerebrovascular events (CVI), arterial and/or venous thrombosis, heart failure (HF), and cardiovascular death (considered as MACE) have been collected 10 years after inclusion.

Results: The prevalence of standard atherosclerotic risk factors was less than 40% in both study groups. Left ventricle ejection fraction (LVEF) was over 45% in more than 90% of patients in both groups (p=0.246) with valvular dysfunction present in 49% of PAPS and 58.1% of sAPS patients (p=0.426). FMD was lowered in 29.4% of PAPS and 29% of sAPS (p=0.971) and carotid atherosclerotic plaques were present in 41.2% of PAPS and 64.5% of sAPS patients (p=0.040). 9.8% PAPS and 12.9% sAPS had coronary artery disease (CAD) (p=0.724) and HF was present in 7.8% PAPS and 3.2% sAPS (p=0.645). MACE occurred in 17.6% of PAPS and 22.6% of sAPS (p=0.585). The new MI occurred in 9.8% of PAPS and 9.7% of sAPS (p=1.000). CVI in 5.9% of PAPS and 3.2% of sAPS (p=0.645) and HF in 7% of PAPS and 12.9% of sAPS (p=0.724). New thrombotic events (arterial and/or venous) occurred in 15.7% of PAPS and 17.2% of sAPS (p=1.000). During the follow-up period, 66.7% of PAPS and 55.2% of sAPS (p=0.313) were treated with aspirin, 25.5% of PAPS and 25% of sAPS with warfarin, and chlorthalidone was administered in 46.8% of PAPS and 53.6% of sAPS (p=0.571). Age (p=0.008), gender (p=0.034), thrombotic APS (p=0.033), hypertension (p=0.003), diabetes mellitus (p=0.043), and cardiovascular manifestations present at the time of APS diagnosis (p=0.035), namely CAD (p=0.001) and HF (p=0.005) were significantly associated with 10y MACE. In our cohort, aPL type and category were not associated with 10y MACE. In a multivariate logistic model, age, hypertension, and HF were independent predictors for 10y MACE (p=0.012, OR 8.406, p=0.032, OR 4.588, p=0.019, OR 20.077, respectively for CI 95%).

Conclusions: APS patients develop new cardiovascular events despite optimal medical therapy. Cardiovascular evaluation at the time of diagnosis and proper cardiologist follow-up with the rigorous treatment of standard atherosclerotic risk factors is of utmost importance.

EFFECTS OF VIRTUAL REALITY IN PATIENTS WITH CHRONIC REFRACTORY PAIN SYNDROMES UNDERGOING A MULTIMODAL PAIN PROGRAM

Keywords: Health services research, Fibromyalgia, Pain

T. Preten1, T. Högé1, P. Ming Azvedo1. 1University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland

Background: Virtual reality (VR) has shown efficacy and safety in reducing pain in various indications. Our department has been using virtual reality applications for several years in the multimodal pain program, where patients also undergo a detailed physical and psychological evaluation, allowing for distinct phenotyping.

Objectives: The aim of this study was to investigate the quantitative and qualitative analytic and anxiolytic effect of a virtual reality (VR) procedure, and to identify patient clusters with a positive response to virtual reality.

Methods: 201 patients with refractory chronic pain syndromes (mainly back pain, primary or secondary fibromyalgia) who participated in a two-week multimodal treatment were included. Of those, 43 performed VR sessions under supervision. Pain (0-10) and anxiety (0-10) were assessed before and directly after a 10-minute VR session (Healthy Mind, France). Multivariate analysis with clinical variables and unsupervised machine learning for clustering analyses by hierarchical agglomerative clustering using the Ward variance minimization algorithm was performed (Python 3.10). In 40 patients, we performed qualitative user experience (UX) assessment of VR by telephone interviews.

Methods: From a large cohort of 181 APS patients included in a study from 2011-2012, year at University Clinical Hospital Center Bezanjiška kosa, Belgrade, Serbia, data for the occurrence of MACE in 10 years of follow-up were evaluated in 82 patients (86.6% females, 62.1% with primary (PAPS), and 37.8% patients with APS associated with systemic lupus erythematosus (SLE) (sAPS)). At the inclusion in all patients, a transthoracic echocardiography study for the assessment of dimensions and functionality of the left and right heart along with valvular functions and morphology has been performed along with color doppler scan of carotid arteries for the intima-media thickness and presence of plaques, and low- and flow-mediated dilatation of the brachial artery (FMD) as markers of subclinical atherosclerosis. Standard atherosclerotic risk factors prevalence was analyzed. Antiphospholipid antibodies (aPL) analysis included the detection of aCL (IgG/IgM), IIF (IgG/IgM), and LA, and all patients were treated according to the valid guidelines by the rheumatologist. Data regarding the occurrence of new myocardial infarction (MI), cerebrovascular events (CVI), arterial and/or venous thrombosis, heart failure (HF), and cardiovascular death (considered as MACE) have been collected 10 years after inclusion.

Results: The prevalence of standard atherosclerotic risk factors was less than 40% in both study groups. HPR Interventions (educational, physical, social and psychological)
Results: Overall, 51% patients experienced a reduction of pain (mean -1.03, baseline 6.15) and 49% a reduction of anxiety (mean -1.36, baseline 4.25) directly after the VR intervention. In 14% pain reduction was ≥3 points (25% for anxiety). Pain increased after the intervention in 15% and anxiety in 7% of the patients. The overall experience with VR was rated as positive in 76%, neutral in 9%, and negative in 14%. Qualitative assessment revealed that several of the non-responders expect a positive outcome in case of a more frequent application of VR. Unsupervised learning indicated the highest positive response in 2/5 clusters. One cluster was characterized by peri-menopausal women with moderate depression and systemic low-grade inflammation. The second cluster was mainly young to middle-aged men with low BMI, hypermobility, anxiety and somatiform pain. Other clusters characterized by failed-back surgery or post-traumatic stress disorders responded less to VR.

Conclusion: Overall, VR was well tolerated and showed a positive short-term response on pain and anxiety. Machine learning algorithms trained in larger cohorts may confirm the prediction of VR response in specific patient subgroups.

Acknowledgements: We thank Chris Lovejoy for the cluster analysis.

**POS1004-HPR INVESTIGATING THE EFFECTS OF COGNITIVE EXERCISE THERAPY APPROACH ON FUNCTIONING, ANXIETY, DEPRESSION AND BIOPSYCHOSOCIAL STATUS OF INDIVIDUALS DIAGNOSED WITH SYSTEMIC SCLEROSIS: A CONTROLLED PILOT STUDY**

Keywords: Systemic sclerosis, Physical therapy/physiotherapy, Rehabilitation

M. O. Tekeli; A. Akoğan; E. Ünal; Hacettepe University Institute of Health Sciences, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey; Hacettepe University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey; Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: Systemic Sclerosis (SSc) with heterogeneous involvement limits the functionality of individuals. Anxiety-depression and biopsychosocial effects are observed due to these functional limitations. Therefore, a biopsychosocial approach is recommended in the disease management of individuals with SSc [1, 2]. The Cognitive Exercise Therapy Approach (BETY) developed on individuals with rheumatism has been presented to the literature as a biopsychosocial-based exercise approach [3].

Objectives: The aim of this study was to investigate the effects of BETY on functionality, anxiety-depression and biopsychosocial status of individuals diagnosed with SSc.

Methods: 24 individuals diagnosed with SSc, 12 of who participated in BETY exercise sessions (Group 1) and 12 in the control group (Group 2) were included in the study. BETY exercise sessions were applied as group exercises 3 days a week for 12 weeks. At the beginning of the sessions and at the end of 12 weeks, functionality was evaluated with the Scleroderma Health Assessment Questionnaire (SHAQ) [4], anxiety-depression status with the Hospital Anxiety Depression Scale (HADS) (2) and biopsychosocial status with the BETY-Biopsychosocial Questionnaire (BETY-BQ) [3].

Results: The mean age of the individuals in the exercise group (44.50 ± 10.16 years) and the control group (44.77 ± 13.63 years), other demographic information and first evaluation parameters were similar (p>0.05). Individuals who participated in all BETY exercise sessions showed a significant improvement in all parameters (p<0.05). In the control group, depression score worsened (p<0.001) while other parameters did not change (p>0.05) (Table 1).

Conclusion: Individuals with SSc who participated in BETY exercise sessions showed improvements in functionality, anxiety-depression and biopsychosocial features which were not seen in the control group. The results obtained from the study were interpreted as an example that BETY, an innovative exercise method on the basis of the biopsychosocial model, can meet this need in the disease management of individuals with SSc, where the importance of biopsychosocial approach is emphasized. It was aimed to investigate the contribution of BETY to the literature by evaluating it on more individuals with SSc and with objective measurement parameters as well as scales.

**POS1005-HPR RELIABILITY AND VALIDITY OF THE CONE EVASION WALK TEST IN KNEE OSTEOARTHRITIS**

Keywords: Cartilage, Comorbidities, Clinical trials

B. Unver1, K. S. Kacamaz2, V. Karatosun3, 1Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey; 2Izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey; 3Dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey

Background: Knee osteoarthritis (OA) can cause a variety of dysfunctions leading to limitations in mobility, gait, and balance that predisposes them to increased fall risk [1,2]. Falls are the leading cause of injury and fracture [3], putting a significant financial burden on the healthcare system. The fall risk is even higher in people with knee OA with a prevalence between 23 and 63% [4]. Another study reported that almost 50% of patients with knee OA experienced falls [5]. Therefore, the identification of fall predictors is essential to minimize fall incidence [6]. The Cone Evasion Walk Test (CEW) evaluates fall risk by the ability to evade obstacles and walking, which provides a versatile assessment including attentional, perceptual, seeing, and several neuromusculoskeletal and movement-related functions and can be performed with or without a walking aid [7].

Objectives: The study aimed to investigate the reliability, validity, and minimal clinically important difference (MCID) of the CEW in people with knee OA.

Methods: Thirty-three patients with knee OA were included. Patients performed trials for the CEW and the Timed up and Go Test on the same day. Between the trials, patients waited for an hour in a sitting position to prevent fatigue.

Results: The CEW was shown to have excellent test-retest reliability and moderate validity (p<0.001). The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the CEW were 0.97, 0.73, and 2.02 respectively. The Pearson correlation coefficient between the CEW and the TUG was 0.72.

Conclusion: The measurements support the use of the CEW to evaluate dynamic balance and obstacle avoidance of knee OA patients. The analysis demonstrated excellent reliability and moderate validity. The low MCID value (2.02) indicated that it is a responsive test to identify small changes in a patient's status. The CEW can be used for a global evaluation of the function and mobility of knee OA patients with little space and equipment, easily and quickly.

**DOES FIBROMYALGIA AFFECT OCCUPATIONAL PRODUCTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS?**

**Keywords:** Work-related issues, Fibromyalgia, Rheumatoid arthritis

O. Hamdi1, H. Boussassa1, S. Miladi1, B. A. Hiba1, L. Souabni1, K. Ouenniche1, S. Kessab1, S. Chekili1, K. Ben Abdelghani1, F. Ala1, A. Laatar1,1 Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia

**Background:** Rheumatoid arthritis (RA) may have a negative impact on patients’ autonomy, quality of life and work productivity. Associated fibromyalgia may further accentuate this issue.

**Objectives:**  We aimed to assess the impact of RA-associated fibromyalgia on occupational productivity.

**Methods:** We conducted a cross-sectional study including RA patients (2010 ACR/EULAR criteria). Patients were divided into two groups: group 1 (G1) including patients with fibromyalgia associated to RA, and group 2 (G2) including patients with RA. Fibromyalgia screening was based on the Fibromyalgia Rapid Screening Tool (FIRST). All patients completed the following questionnaires: Workplace Activity Limitations Scale (WALS) which is composed of 11 items (total score varying between 0 and 33), Work Productivity and Activity Impairment (WPAI) and Euro-Qol (EQ-5D). We compared the two groups of patients using the Student’s t-test. The significance threshold was set at a p-value of 0.05.

**Results:** Our study included 80 patients (G1; N=40 and G2; N=40) with an average age of 59±9 years [42-77] for G1, and 53±10 years for G2 [37-74]. The gender-ratio was 0.05. All the patients in G1 and 80% of patients in G2 held a job. The mean RA duration was 119±28.4 years. RA was erosive and ACA/PF positive in 90% and 85% of cases, respectively. The mean delay between fibromyalgia and RA diagnosis was 49±7 months. The mean Disease Activity Score 28 (DAS28-ESR) was 5 in G1, and 3.97 in G2. The reduction of work activity was greater in G1 compared to G2: the mean WALS in G1 was 18±2.7 vs 10.2±1.5 in G2; p= 0.01. The WPAI showed that the mean number of work hours missed due to RA was significantly higher in G1 compared to G2: 10.2±8.9 hours vs 4.3±3.8 hours (p< 0.01). The mean absenteeism rate was higher in G1 compared to G2: 20.5±1.9% in G1 vs 10.2±0.5% in G2 (p= 0.02). The percentage of overall impairment of health-related-activity was higher in G1 compared to G2: 50±8.6% in G1 vs 30±4.4% in G2 (p= 0.01). The mean self-rated health status using the EQ-5D VAS was 72.08±7% in G1 and 48±3.5% in G2 (p=0.05). The most affected dimensions in the EQ-5D for both groups were in the first place pain and discomfort, and secondly mobility. Loss of autonomy was found in 7 patients (37.5%) in G1 and 3 patients (75%) in G2. Depression and/or anxiety occurred in 45% of cases in G1, and 22.5% of cases in G2, respectively.

**Conclusion:** Our study showed that RA-associated fibromyalgia has a negative impact on work performance and productivity. This association also seems to alter the quality of life.

**EXPERIENCES OF PARTICIPATION IN GOAL SETTING PRIOR TO RHEUMATOID TEAM REHABILITATION – A JOINT VENTURE**

**Keywords:** Qualitative research methods, Rehabilitation

L. Skovby Nielsen1,2, J. Primidahl1,2, B. Clausen3, A. Bremender1,2,5,6,1 Danish Hospital for Rheumatic Diseases, The Research Unit, Sønderborg, Denmark; 2University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 3Sano Denmark, Sano Middelfart, Middelfart, Denmark; 4Hospital of Southern Jutland, University Hospital of Southern Denmark, Aabenraa, Denmark; 5Lund University, Department of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden; 6Sørenshtu Research and Development Centre, Spennshult, Halmstad, Sweden

**Background:** Patient involvement in the goalsetting process and use of shared decisions increases adherence to rehabilitation and support patients’ motivation to achieve the goals (1). However, the shared decisions that are essential for goal setting during a rehabilitation process may be compromised by patients’ lack of ability to participate actively in setting goals, inadequate skills among health professionals (HPs) to facilitate goal setting and poor organizational conditions such as insufficient time [2]. This study focuses on a Danish multi-professional team rehabilitation context where, over several years, work has been done to improve the prerequisites for goal setting, both by organizational changes and by educating and preparing HPs as well as patients for the goal setting process.

**Objectives:** To understand how patients with rheumatic musculoskeletal diseases (RMDs) perceive participation in the goal setting process prior to multi-professional team rehabilitation.

**Methods:** Individual semi-structured interviews were performed with 22 patients (median 49 years, 17 female), who were to be admitted to multi-professional team rehabilitation for patients with RMDs at one of two Danish rehabilitation centres. We applied qualitative content analysis with an inductive approach. All participants had received information about goal setting prior to admission and the team used supportive tools and motivational interviewing to facilitate the goal setting process.

**Results:** The analysis derived one overarching theme, goal setting was viewed as a joint venture between the patients and the team, where capacities and resources were shared in order to formulate one or more goals. Three sub-themes emerged from the analysis (Table 1): 1) Responsibility during goal setting was experienced as a shared responsibility between the patient and the team, where active involvement in the goal setting process added to patients’ feeling of responsibility. For others, goal setting was perceived as a responsibility that solely rested with the team of HPs, who were considered to be the experts. 2) Being dressed for goal setting reflected whether patients felt prepared to take part in goal setting. Written and oral information prior to rehabilitation evoked thoughts on potential goals and previous experiences with rehabilitation made patients feel more qualified for setting goals. Others perceived goal setting as very difficult, partly because it felt like a huge commitment or due to lack of information.3) Being an equal member of the team referred to the interaction with the HPs. Patients felt they were seen as whole persons, and they felt acknowledged and respected. On the other hand, some felt as outsiders and considered HPs as authorities, causing a feeling of nervousness and insecurity related to the validity of the patients’ wishes and expectations.

**Conclusion:** Despite a clinical practice where key areas of importance to successful patient-centred goal setting has been implemented, goal setting is still perceived as a challenge for some patients with RMDs. Future studies should uncover whether the level of health literacy among patients with RMDs bears importance for shared decisions and goal setting prior to rehabilitation.

Adaptive immunity (T cells and B cells) in rheumatic diseases

Keywords: Adaptive immunity, Rheumatoid arthritis, Synovium

E. A. James, C. Rimzï, S. Possoz, J. Carlin, W. Kwok2, S. E. Ong, J. Buckner. 1Benaroya Research Institute, Center for Translational Immunology, Seattle, United States of America; 2Benaroya Research Institute, Center for Translational Immunology, Seattle, United States of America; 3Benaroya Research Institute, Clinical Member, Seattle, United States of America; 4University of Washington, Pharmacology, Seattle, United States of America

Background: Rheumatoid arthritis (RA) is a T cell mediated autoimmune disease in which citrullinated self-antigens are recognized by anti-citrullinated protein antibodies (ACPA) and T cells. To date, the majority of T cell studies have been performed using peripheral blood and have focused on well-documented ACPA targets. Studies of disease-affected tissue are needed to confirm and extend observations that have been made through study of peripheral blood T cells.

Objectives: T cell subsets and targets that have not been observed in peripheral blood are likely to be important and understudied for the identification of the antigen specific responses that underlie RA. We sought to generate novel insights about T cell phenotypes and antigenic targets by performing multicolor flow cytometry analysis and HLA peptidomics studies of synovial tissue samples from subjects with RA.

Methods: Synovial tissue was obtained from 7 subjects with seropositive RA, 4 subjects with seronegative RA, and 8 subjects with osteoarthritis, all of whom had undergone arthroplasty procedures. Synovial cell suspensions were obtained from tissue by mincing, digestion in collagenase I, and filtration. These were subjected to multicolor flow cytometry analysis to gain insights about the lymphocyte and non-lymphocyte cell subsets present. After confirming leucocyte antigen (HLA) protein expression by flow cytometry, additional tissue was solubilized in lysis buffer and HLA class I and HLA-DR complexes were captured (separately) on affinity columns. HLA-bound peptides were eluted, concentrated, and peptide spectra were identified by LC-MS/MS analysis. The resulting databases were then analyzed using a human protein database. Mass shifts associated with each assigned sequence were utilized to identify post-translational modifications – most notably citrullination of native arginine residues. Comprehensive libraries of the HLA-Class I and HLA-DR-bound peptides from each individual were imported into a custom database, which was then used to catalogue the most prevalent self-proteins for each patient type. T cell assays were then performed to demonstrate the immunogenicity of novel targets and probe T cell antigen specificity in tissue.

Results: Flow cytometry analysis of synovial tissue derived cells demonstrated that fibroblasts (including fibroblast-like synoviocytes), monocytes, and B cells were all present in tissue. In particular, fibroblasts and monocytes showed evidence of inflammation, including upregulated levels of HLA-DR expression. Similar numbers of CD4+ and CD8+ T cells were present in tissue, with phenotypes that included various memory subsets but essentially no naïve cells. In comparison with peripheral blood, T cells from synovial tissue showed evidence of recent activation, expressing higher levels of CD95, CD71, PD-1, ICOS, and CD28. The most prevalent self-proteins in the HLA-DR-bound peptidome from the synovial tissue of RA subjects included expected targets such as vimentin, alpha-1-antitrypsin, fibrinogen, collagen, histones, and BIP but also contained novel targets such as fibronectin, gelsolin, and proteoglycan 4. Prevalent self-proteins in the HLA-Class I-bound peptidome included well-studied CD4+ T cell targets such as vimentin, alpha-1-antitrypsin, fibrinogen, collagen, and histones, and BIP but also contained novel targets such as caspase-14, stromelysin-1, and filamin-A. T cell assays using the immunogenicity of expected targets and the new candidate antigen gelsolin, in particular, a comparatively robust population of aggregan specific T cell targets was present in tissue.

Conclusion: Our findings demonstrate that flow cytometry and HLA peptidomics analysis of synovial tissue can provide novel insights about the phenotype and antigen specificity of T cells in RA. Further characterization of T cell response to these targets is needed, including those that recognize novel antigens, has the potential to provide important new insights about the character of antigen specific T cell responses that promote the development of RA.

Innate immunity in rheumatic diseases

Keywords: Lungs, Innate immunity, Rheumatoid arthritis

C. Kärman Mährä, T. Jylhä, M. Laakso, J. Vikgren, A. J. Johnson, G. Larsson, D. Glinati, K. Stubendorff, K. Svensson, I. Gjertsen, A. Rudin, A. C. Lundell, A. K. H. Ekwall. 1Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden; 3Institute for Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Department of Radiology, Gothenburg, Sweden, 4Skaraborg Hospital, Skövde, Sweden, Department of Rheumatology, Skövde, Sweden

Background: The role of the lung for the initiation and progression of rheumatoid arthritis (RA) is still unclear [1]. Up to 10% of RA patients develop severe treatment resistant lung disease [2]. Understanding early disease mechanisms is of great importance. Neutrophils are key players in RA pathogenesis and are recruited to the lungs early in the disease [3]. In RA, circulating neutrophils display an activated phenotype and neutrophil activation markers predict joint destruction and development of extra-articular nodules [4]. Neutrophil activation status has not been studied in relation to pulmonary abnormalities (PA) in early untreated RA (eRA).

Objectives: To determine whether there is an association between peripheral neutrophil phenotypes and presence of PA on chest high-resolution computed tomography (HRCT) in eRA.

Methods: Clinical data and blood were collected, and HRCT performed at diagnosis on 30 consecutive anti-citryllated protein antibody (ACPA) and/or rheumatoid factor (RF) positive eRA patients, HRCTs were evaluated for the presence and extent of RA-associated parenchymal, airway and/or pleural abnormalities. Expression of phenotype markers on neutrophils separated by density was determined by flow cytometry. Levels of calprotectin, ACPA and RF were measured using immunoassays. An initial principal component analysis was used to visualize the relationships of the multidimensional data followed by univariate analysis of the strongest associations.

Results: The median patient-reported symptom duration was 6 months, 20% of the patients were current smokers and the mean disease activity was moderate in this seropositive eRA cohort. The frequency of having any PA detected by HRCT was 60%, Airway abnormalities were present in 50%, nodules in 43% and interstitial lung abnormalities (ILA) in 10%. Unsupervised multivariate factor analysis showed clustering of “any PA” with neutrophil activation, parameters of inflammation and RF titres (Figure 1A). Univariate analysis confirmed a significantly increased CD11b and decreased CD62L expression on neutrophils indicating activation in patients with PA as compared to no PA. Titres of RF, but not ACPA, correlated with expression of the neutrophil activation marker CD11b. A stratified analysis demonstrated that airway involvement was the PA subtype with the strongest association with neutrophil activation (CD11b 1.3-fold, p=0.014 and CD62L 0.6-fold, p=0.003 in patients with airway abnormalities as compared to no PA) and with RF IgM titres (8.8-fold, p=0.0002) (Figure 1B).

Conclusion: We report a significant association between radiographic airway findings and activation of circulating neutrophils in early RA supporting a role of innate immunity and the lung in disease onset. Our results also indicate different contributions of RF and ACPA in the RA pathogenesis. Parts of this abstract was presented 15th September 2022 on a national rheumatology meeting in Gothenburg, Sweden.

MACROPHAGE EXTRACELLULAR TRAPS PROMOTE FIBROBLAST-LIKE SYNOVIOCYTES PROLIFERATION AND PROINFLAMMATORY CYTOKINE IN RHEUMATOID ARTHRITIS

Keywords: Innate immunity, Synovium, Rheumatoid arthritis

W. Weng1, Y. Jiang1, S. Zhong1, Y. Pan1. 1. Third Affiliated Hospital of Sun Yat-Sen University, Department of Rheumatology and Immunology, Guangzhou, China

Background: Macrophage Extracellular Traps (METs) play an important role in the promotion of tissue injury, inflammation progression and autoimmune diseases.

Objectives: This study aims to investigate the effects of METs on the proliferation and expression of proinflammatory cytokines in fibroblast-like synoviocytes (FLS) in patients with rheumatoid arthritis (RA).

Methods: Synovial tissues of RA patients and traumatic controls undergoing joint replacement in our hospital were collected. The FLS of RA patients were cultured in vitro. Peripheral blood mononuclear cells (PBMC) were isolated from RA patients and differentiated into macrophages by M-CSF. The macrophages were cocultured with serum of RA patients and healthy controls. SYTOX green, which stained the DNA released from cells and was a common method for detecting ETs, was added to observe the formation of METs. The expressions of CD68 and Cith3 in synovium were detected by immunofluorescence. METs were isolated and purified from THP-1-derived macrophages and co-incubated with FLS. The RNA expressions of proinflammatory cytokines TNF-a and IL-1β of RA-FLSs were detected by qPCR. The proliferation ability of RA-FLSs was detected by CCK-8 assay.

Results: We found the enrichment of macropores labeled with CD68 and Cith3 in RA synovial tissues but not in traumatic controls. Immunofluorescence co-localization assay displayed that most Cith3 were distributed around CD68, suggesting that macrophages may be the main source of ETs (Figure 1A). PBMC induced macrophages co-incubated with serum from RA patients showed the formation of strip-like METs, while no obvious METs were observed with serum from healthy controls (Figure 1B). Purified METs were isolated and co-incubated with RA-FLSs for 48h. TNF-a and IL-1β were significantly overexpressed, and the proliferation of RA-FLSs was promoted (Figure 1C-D).

Conclusion: METs were detected in RA synovium but not in traumatic controls. The autointoMTides or inflammatory cytokines presented in the serum of RA patients may be associated with the increased METs formation in RA. In vitro experiments, METs could promote the proliferation and proinflammatory cytokines expression of RA-FLSs, suggesting that clearing or blocking the formation of METs may be a new therapeutic target for RA.

DIFFERENT SYNOVIAL MACROPHAGE AND FIBROBLAST SUBSETS, EXPRESSION PROFILES AND CELL-CELL INTERACTIONS CHARACTERISE SEX DIFFERENCES IN CHRONIC INFLAMMATORY JOINT DISEASES

Keywords: Synovium, Inflammatory arthritis, -omics

R. Michieli1, A. Khmelykyska1, C. Pattil2, E. Vallejo-Yague3, M. Elbia4, K. Buerki1, O. Distler1, A. Ciurea1, C. Ospelt1. 1. University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; 2. University Hospital Zurich, Zurich, Department of Pathology, Zurich, Switzerland; 3. ETH Zurich, Institute of Pharmaceutical Sciences, Department of Chemistry and Applied Biosciences, Zurich, Switzerland

Background: Chronic inflammatory joint diseases differ between males and females in terms of disease manifestation, treatment response and radiographic progression. A molecular basis that could explain these differences has yet to be identified.

Objectives: The study aimed to find differences in synovitis at histology and transcriptome level between males and females with chronic inflammatory joint diseases.

Methods: Synovial tissue was obtained by ultrasound-guided biopsy from inflamed joints from 5 males and 5 age- and disease-matched females. Histological analysis included Krenn score and synovial pathotype. Single-cell RNA-sequencing (scRNA-seq) libraries were prepared with 10X Genomics and sequenced with NovaSeq 6000. We performed additional histological analyses (Krenn score and CD68 staining) on synovial tissue samples obtained from joint replacement surgery in 13 males and 13 age- and synovial pathotype-matched females with rheumatoid arthritis. The following R packages were used for bioinformatic analysis: Cell Ranger, Seurat, Harmony and CellChat. KEGG gene set enrichment analysis was performed with ClusterProfiler.

Results: We included 4 psoriatic arthritis, 2 rheumatoid arthritis, 2 undifferentiated arthritis and 2 peripheral spondyloarthritis patients. Females and males did not significantly differ in baseline characteristics: mean age was 46.2 years in females, 46.8 years in males; 2 knees and 3 wrists were biopsied per sex; mean swollen joint count was 6.8 in females and 8.2 in males. Histological analysis of the sexes showed no significant differences: synovitis was moderate in both sexes (mean Krenn total score 4.0) and pathotypes were balanced in males (1 diffuse-myxoid, 2 lympho-myxoid, 2 pauci-immune) and females (1 diffuse-myxoid, 1 lympho-myxoid, 1 pauci-immune, 2 ungradable). 41,041 cells were integrated for scRNA-seq analysis (female 21,636 and male 19,378 cells). Pseudobulk variance analysis showed a significant correlation of sex with principal component (PC) 3, accounting for 12.6% of the sample variation (Figure 1A). In addition to the sex-specific genes XIST and PRS4Y1, the following genes were main drivers of the PC3 variation: H19, CXCL9 and CXCL10. Diagnosis was not significantly associated with any PC. Comparison of the individual cell cluster proportions showed that LYVE1+ macrophages (MC) were significantly more prevalent in females (4.9% in males versus 13.7% in females, p = 0.03) (Figure 1B). In confirmatory histological analysis, consistent with the known location of LYVE1+ MC in the lining layer, both Krenn lining score (mean SD score in males 1.85 (0.69) and 2.08 (0.76) in females) and CD68 lining score (mean SD score in males 1.77 (1.17) and 2.08 (0.95) in females) were higher in females but did not reach statistical significance. Differential gene expression analysis showed that mainly in synovial fibroblasts (SF) genes were differentially expressed between males and females (n = 1944). In SF, upregulated genes in males led to a significant enrichment of proinflammatory pathways (TNF pathway, NF-kappa B pathway, IL-17 pathway). In contrast, upregulated genes in females were significantly associated with ECM-receptor interaction, focal adhesion, protein digestion and absorption pathways (Figure 1C). In cell-cell interaction analyses, most outgoing signaling was observed in SF while MC represented most receiving cells; IL6 and CXCL signaling pathways were significantly enriched in males, and COLLAGEN and THY1 signaling pathways were enriched in females (Figure 1D/E).

Conclusion: Our study shows potential important differences in synovitis between males and females with chronic inflammatory joint diseases. In females, synovitis was characterized by abundance of LYVE1+ MC and SF expressing

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.2630
extracellular matrix-associated genes. In contrast, male SF showed a proinflammatory transcriptional profile. These sex-specific differences should be considered in research studying synovitis and may warrant sex-specific therapeutic approaches.

Mankaia1,2, MRC Weatherall Institute of Molecular Medicine, Department of Oncology, Oxford, United Kingdom; University of Oxford, Department of Oncology Oxford, United Kingdom; Leeds Institute of Rheumatic and Musculoskeletal Medicine, Division of Musculoskeletal Disease, Leeds, United Kingdom; Leeds Biomedical Research Centre, Department of Rheumatology, Leeds, United Kingdom

Background: Anti-cyclic citrullinated peptide ( CCP) antibody positive individuals with musculoskeletal ( MSK) symptoms but no clinical synovitis are at elevated risk of developing rheumatoid arthritis ( RA) [1]. Whilst risk stratification is possible, specific immunological changes underpinning the transition from pre-RA to clinical arthritis remain unclear.

Objectives: We aimed to define markers of rapid progression across immune-cell subsets to enable early differentiation of those who will progress to arthritis in ‘ high-risk’ anti-CCP positive individuals.

Methods: Peripheral blood mononuclear cells ( PBMCs) were collected from anti-CCP positive individuals with MSK symptoms but no clinical synovitis ( CCP+ at-risk) [2]. We performed single cell RNA sequencing ( scRNAseq) of PBMCs from 10 CCP+ at-risk individuals (6 CCP+ progressors, 4 CCP+ non-progressors) collected at baseline and follow-up time points (i.e. progression to arthritis in the CCP+ progressors). All subjects had high positive anti-CCP levels (>3x ULN) and were HLA-DR shared epitope positive with median time to progression in progressors being 4 months. Analysis was performed in R using SingleR for subset annotation and Seurat for differential gene expression analysis between progressors and non-progressors and across time points.

Results: Examining all subsets, we noted a generalised increased Type 1 interferon response in non-progressors, with B cells (n=8,659) showing the most prominent divergence between groups. Within B cells we observed 334 differentially expressed genes (DEG) in CCP+ progressors versus non-progressors at baseline and 143 DEG at follow up (padj<0.05), with 77 DEG consistent across timepoints. At baseline, CCP+ progressors demonstrated upregulation of genes associated with B cell antigen-presentation, including Class II MHC molecules, CD83 and CD74. Conversely, interferon stimulated genes (ISG) were enriched in the CCP− non-progression DEG. Notably, this ISG signature ceased at follow-up (median 14 months). Examining the DEG per B cell subset, we noted that upregulation of genes associated with B cell antigen-presentation is found across naive, unwswitched memory and switched memory B cells in CCP+ progressors at baseline. In contrast, ISG upregulation is specific to a separate subset of interferon-responsive B cells. At baseline, these cells form a significantly greater proportion of all B cells in the CCP+ non-progression group versus the progressor group (178% versus 2.6%, p<0.0013). At follow-up, the proportions are comparable between the two groups (2.5% in non-progression versus 3.4% in progressor, p=0.08), reflecting the transient nature of ISG upregulation.

Conclusion: CCP+ at risk individuals with imminent arthritis demonstrate a distinct B cell gene expression profile. Imminent progression is associated with markers of B cell mediated antigen presentation across multiple subsets whereas non-progressors demonstrate transient over-expression of ISGs driven by expansion of a subset of interferon-responsive B cells. These data reveal mechanistic insights into the early divergence between these groups and the development of RA.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that affects joints and other parts of the body. The pathogenesis of RA is still not fully understood, and finding effective treatments remains a challenge. Single cell RNA sequencing (scRNAseq) has been used to study the heterogeneity of immune cells in RA. The aim of this study was to observe the preventive effect of low-dose IL-2 in collagen-induced arthritis, and to characterize the cellular mechanisms underlying such an effect.

Objectives: To study the pathogenesis of RA, we used single cell RNA sequencing to examine the genetic expression of immune cells in RA. We aimed to identify the cellular mechanisms underlying the preventive effect of low-dose IL-2 in collagen-induced arthritis.

Methods: We used scRNAseq to study the genetic expression of immune cells in RA. We compared the expression of genes associated with immune cell activation and differentiation in RA patients and healthy controls. We also examined the effect of low-dose IL-2 on the genetic expression of immune cells in collagen-induced arthritis.

Results: We found that the expression of genes associated with immune cell activation and differentiation was significantly higher in RA patients than in healthy controls. We also found that low-dose IL-2 treatment reduced the expression of these genes in collagen-induced arthritis.

Conclusion: Our findings suggest that low-dose IL-2 treatment can prevent the development of RA by reducing the expression of immune cell activation and differentiation genes.
group, the proportion of Th17/Treg in CIA group was significantly higher than healthy control group. Compared with CIA model group, Th17/Treg in all intervention groups (0d,7d,14d,21d-IL-2) were significantly lower.

Conclusion: Early administration of low-dose IL-2 may help reduce the incidence of arthritis and disease activity in CIA by restoring Th17/Treg balance, but it has time heterogeneity.

Background: Despite of recent developments in therapeutic agents for rheumatoid arthritis (RA) patients[1], it is reported that half of the patients are unable to achieve remission even with existing drugs[2]. Therefore, there is an urgent need to gain mechanistic insight into treatment resistance. Nowadays, single-cell RNA sequencing (scRNA-seq) technology have dramatically improved our understanding of the heterogeneity in synovial cells. However, it has not been fully elucidated how the cell clusters are related to treatment response, especially in Asian races[3].

Objectives: We intend to analyze the RA synovium from Japanese patients based on single-cell transcriptomics to explore the pathological key players related to treatment resistance.

Methods: Synovial specimens were collected from 31 RA patients using an ultrasound-guided needle biopsy. The proportion of 5 immune cell subsets (CD4+ T cells, CD8+ T cells, B cells, NK cells, monocytes) and mesenchymal (synovial fibroblasts (SF), endothelial cells, mural cells) were analyzed by flow cytometry. CD45+ and CD45- live cells were isolated, and scRNA-seq libraries were prepared using the 10x chromium system.

Results: We classified the patients into the following three groups based on treatment status at the time of biopsy; treatment-naive, inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs-IR), or biological DMARDs (bDMARDs-IR). The proportion of CD8+ T cells, especially GZMB+ GZMK+ CD8+ T cells, was significantly lower in csDMARDs-IR patients compared to treatment-naive patients. This population was characterized by enhanced expression of IFNG and GZMK, the cooperative inducers of IL-6 production from SF. Meanwhile, an increased proportion of SF, especially THY1+ sublining and CD45+ sublining, was observed in csDMARDs-IR and bDMARDs-IR patients. Intriguingly, by integrating gene set variation analysis (GSVA) with transcriptomic data of cytokine-stimulated SF in vitro, THY1+ sublining was indicated to be activated independently of the effects of inflammatory cytokines (e.g., TNF-α, IL-1β, IFNα) (Figure 1). Collectively, this SF subpopulation was inferred to be less susceptible to cytokine-blocking agents such as IL-6 receptor or TNF-α inhibitors.

Conclusion: The synovial analysis has the potential to be useful in parsing the mechanism of treatment resistance in Japanese RA patients, and gaining insights into novel therapeutic targets.

A NOVEL DRUG COMBINATION OF IGURATIMOD AND TOFACITINIB ALLEVIATES RHEUMATOID ARTHRITIS AND SECONDARY OSTEOPOROSIS

Keywords: Osteoporosis, Rheumatoid arthritis, Animal models

J. Chen1,2, M. Li3,4, Q. Che1,2, Y. Kou4,5, X. Rong4,5, X. Zhang1,2, O. Shu4,5, 1Qilu Hospital, Cheeolo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; 2Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Jinan, China; 3School and Hospital of Stomatlogy, Cheeolo College of Medicine, Shandong University, Department of Bone Metabolism, Jinan, China; 4Shandong University, Center of Osteoporosis and Bone Mineral Research, Jinan, China; 5School and Hospital of Stomatlogy, Cheeolo College of Medicine, Shandong University, Department of Bone Metabolism, Jinan, China

Background: At present, specific immune targeted therapeutics including biologics and kinase inhibitors has made significant progress in Rheumatoid arthritis (RA). However, the response to targeted therapies in some refractory RA patients suggests more attention should be paid on cell death pathways, such as pyroptosis. Pyroptosis is a proinflammatory cytokine that plays a fundamental role in the pathogenesis of RA, which could induce pyroptosis in monocytes and macrophages and cause the destruction of bone and cartilage. Iguratimod (IGU) has been confirmed as a highly efficacious and safe conventional synthetic disease-modifying...
anti-rheumatic drug for RA in Asia. Whether the combination of IGU and Tofacitinib (TOF), the Janus kinase inhibitor, would be better partner need to be elucidated.

**Objectives:** To evaluate the therapeutic effect of IGU and TOF on active RA and secondary osteoporosis in collagen-induced arthritis (CIA)+TNF model.

**Methods:** In this study, hematoxylin and eosin (HE) staining were used to evaluate the pathological changes in ankle joints of CIA+TNF model. Immunohistochemistry (IHC) were used to evaluate the level of pyroptosis related proteins in synovial tissue. We performed Micro-computed tomography (Micro-CT), HE staining and IHC to analyze the trabecular bone changes in distal femoral metaphysis to investigate the destruction of knee joint.

**Results:** After 6 weeks treatment of IGU and/or TOF, the diameter of ankle joint and the level of interleukin (IL)-18, IL-1 of CIA+TNF model. Immunohistochemistry (IHC) were used to evaluate the level of pyroptosis related proteins in synovial tissue. We performed M group. HE staining showed that only a small amount of inflammatory cell infiltration and less pannus were seen in synovial tissue of both monotherapy and combination group, when compared with the CIA+TNF group. Of importance, the pyroptosis related proteins, such as gasdermin D (GSDMD), nucleotide-binding domain (NOD)-like receptor protein 3 (NLRP3), caspase-1, and IL-1β were significantly less expression in synovial tissue of combination group compared with the CIA+TNF group. Both the osteoblast bone formation and osteoclast bone absorption were sharply reduced in CIA+TNF model. However, the bone destruction was significantly alleviated and bone turnover rate was remarkably increased in combination group, detected by Micro-CT, HE staining and IHC.

**Conclusion:** The TOF-IGU combination synergistically alleviated the disease severity of the CIA model, including relieving joint inflammation and bone erosion, with suppressing the activation of the NLRP3 inflammasome and reducing GSDMD expression.

**Background:** The gut microbiota has been related to rheumatoid arthritis (RA), inflammation, and its severity. Interstitial lung disease (ILD) causes high morbidity and mortality in RA patients. However, the association between gut microbiota and RA- associated ILD (RA-ILD) is still unknown.

**Objectives:** To analyze the gut microbiota and gut permeability in RA-ILD patients.

**Methods:** Nested case-cohort study of 2 prospective cohorts of patients with RA and with and without ILD. The cohorts were matched for age, sex, and time of RA evolution. All patients systematically underwent high-resolution computed tomography (HRCT) and pulmonary function testing (PFT) on the diagnosis of ILD. The ILD was defined according to the lung biopsy or HRCT based on the standard criteria of the American Thoracic Society/European Respiratory Society, the progression was defined as the worsening of the FVC > 10% or DLCO > 15%. The gut microbiota was measured by the 16S rRNA gene and the sequences were processed using the Quantitative Insights into Microbial Ecology (QIMME2). Serum lipopolysaccharide-binding protein (LBP) and lipopolysaccharide (LPS) were measured as markers of gut permeability.

**Results:** Thirty-five RA-ILD and 35 RA without ILD were included. Table 1 shows the baseline characteristics. After a median (SD) period of 66.1 (472) months, pulmonary progression criteria had observed in 13 patients (37.1%). Compared with controls, RA-ILD had higher values of DAS28-ESR (p=0.032) and higher HAQ scores (p=0.003). They also had higher levels of serum LPS (p = 0.007) and more abundance of Streptococcus genus (p = 0.087), as well as a lower abundance of Slackia (p = 0.022) and Paraprevotella genera (p = 0.082). The RA-ILD with progression had a higher abundance of Streptococcus genus (p = 0.090) and a lower abundance of Slackia genus.

**Conclusion:** RA-ILD patients showed increased gut permeability and also displayed a different pattern of gut microbiota associated with ILD diagnosis and progression. These findings may enable the discovery of potential RA-ILD biomarkers.

A NOVEL PAD2/4 BISPECIFIC ANTIBODY BLOCKS PAD2 ACTIVITY IN VITRO AND DELAYS DISEASE PROGRESS IN CIA-PADS MODEL

Keywords: Animal models, Rheumatoid arthritis

B. Chen1, H. Sun1, N. Ding2, C. Zhang1, A. Chen3, 1Shanghai Qilu Pharmaceutical R&D Center Ltd, Department of Immunology and Inflammation, Shanghai, China; 2Ningbo Medical Center Lihuili Hospital, Department of Rheumatology, Ningbo, China

Background: Peptidyl arginine deaminase (PAD) catalyzes the conversion of arginine residues to citrulline. With the breakdown of self-tolerance, citrullinated antigens become neo-antigens, potentially triggering autoimmune responses. PAD2 and PAD4 are the most strongly implicated PAD isoforms in RA at both genetic and cellular levels. In RA synovial tissue, neutrophil extracellular traps (NETs) are thought to be the major source of PAD2 and PAD4. However, recent findings indicate that neutrophils could secrete PAD2 and express membrane-bound PAD4, which can also catalyze citrullination. Although small-molecule PAD inhibitors such as GSK-484 and AFM-30a have shown good efficacy in PADs enzymatic inhibition assay, no small-molecule PAD inhibitors have entered the clinical stage yet. To avoid off-target effects and disrupting intracellular PAD function, PAD2/4 bispecific neutralizing antibodies may be ideal. Here, we generated a novel and potent PAD2/4 bispecific antibody that is able to block PADs activity both in vitro and in vivo.

Objectives: To develop a novel, highly potent PAD2/4 bispecific blocking antibody to treat rheumatoid arthritis.

Methods: An IgG-ScFv-structure PAD2/4 bispecific antibody was made from hybrido- ma-derived, humanized PAD2, and PAD4-specific monoclonal antibodies. PAD inhibition was determined by BAEE biochemical assay and ABAP assay using Histone H3 as the substrate. Antibody affinity was measured by Biacore. 15 synovial fluid samples from RA patients were used to test the inhibition efficacy of PAD2, PAD4, and PAD2/4 bispecific blocking antibodies by ABAP assay. The induction of collagen-induced arthritis (CIA) was described previously [1]. CIA-PADS model was induced by immunizing 50 ug human PAD2 and 50 ug human PAD4 together with bovine type II collagen. Each treatment group consisted of 11 mice that were given the PAD2/4 bispecific antibody or control IgG 50 mg/kg i.p. twice a week.

Results: PAD2-mAb, PAD4-mAb, and PAD2/4 bispecific antibodies exhibit high affinity and potent PAD inhibition activity in both BAEE biochemical assay and ABAP assay (Table 1). In RA synovial fluid inhibition assay, the PAD2/4 bispecific antibody showed complete inhibition of PADs activity at 10nM concentration, but not PAD2-mAb, PAD4- mAb, or GSK484 (Figure 1A), indicating that RA synovial fluid consists of both PAD enzymes. In in vivo model, we demonstrated that co-immunization of PAD2 and PAD4 proteins significantly increased the disease severity, and treatment with the PAD2/4 bispecific antibody decreased the activity disease (Figure 1B).

Conclusion: We have generated a novel anti-PAD2/4 bispecific blocking antibody with potent inhibitory activity in vitro. Furthermore, the blocking activity is also validated in RA patients' synovial fluid and in a novel CIA-PADS model. Additionally, we first demonstrated that co-immunization of PAD2 and PAD4 proteins could increase the disease severity, indicating PAD2 and PAD4 may play an important role in RA disease pathogenesis. In summary, Our PAD2/PAD4 bispecific Ab may provide a novel therapeutic approach towards the treatment of rheumatoid arthritis.

ROLE OF THE SIGNALING LYMPHOCYTE ACTIVATION MOLECULE FAMILY IN RHEUMATOID ARTHRITIS COMPLICATED WITH INTERSTITIAL LUNG DISEASE

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Lungs

Q. Che1,2, J. Chen1,2, Y. Zhang1,2, C. Ren1,2, X. Zhang2, W. Hongxing2,3, Q. Shu1,2.

1Qilu Hospital, Cheelope College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; 2Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Qilu Hospital, Jinan, China; 3Qilu Hospital, Cheelope College of Medicine, Shandong University, Department of Clinical Laboratory, Jinan, China; 4Shandong Engineering Research Center of Biomarker and Artificial Intelligence Application, Department of Clinical Laboratory, Jinan, China

Background: Intstitial lung disease (ILD) is the most common extra-articular complication of rheumatoid arthritis (RA). The prevalence of RA with ILD is approximately 20% and the risk of ILD is significantly higher in RA patients than in healthy controls [1]. The pathogenesis of RA-ILD has not been elucidated, although various genetic, immunological, and environmental factors have been suggested to be involved in its development and progression [2]. Therefore, it is crucial to explore new targets and predictors of RA-ILD pathogenesis.

Objectives: To explore the common pathogenic mechanisms involved in the initiation and progression of RA-ILD.

Methods: Synovial samples of RA (GSE55235), lung samples of ILD (GSE53845 and GSE81292) were extracted from the Gene Expression Omnibus (GEO) database. Differentially expressed genes (DEGs) analysis, weight gene co-expression network analysis (WGCNA) and Consensus Cluster were implemented with R language. Enrichment analysis and shared hub gene analysis were then performed. The function of selected gene signatures and hub genes were validated in external datasets (synovial tissues of RA (GSE55457) and RA-associated usual interstitial pneumonia (RA-UIP) (GSE199152)), in terms of single cells level, RA-ILD patients and our collagen-induced arthritis (CIA) relative ILD animal model.

Results: The ILD relative gene signatures which contained 90 shared genes was obtained (Figure 1 A). KEGG pathway enrichment analysis identified cytokine-cytokine receptor interactions and chemokine signaling pathways (Figure 1 B). CytobHubba selected 17 hub genes as shown Figure 1 C. Validated the 17 hub genes in lung tissue samples from three RA-UIP patients and four non-UIP controls with the external database (Figure 1 D). In single cell port, the surface molecules of B cells, CD19, CD27, CD38, CD79A, SLAMF1, SLAMF2 and SLAMF7 can be detected in RA synovial tissues and lung samples of ILD (Figure 1 E). The SLAMF1, SLAMF2 and SLAMF7 in PBMCs of RA-ILD patients were highly expressed (Figure 1 F). Furthermore, we constructed the CIA+TNF animal model , whose lung pathology showed ILD-like manifestations (Figure 1 G), together with an increased infiltration of B cells, especially those expressing SLAMF1, SLAMF2 and SLAMF7 in both synovial and pulmonary tissues (Figure 1 H).

Conclusion: Our study explored the common pathogenic mechanisms of RA and ILD, identified the shared 17 hub genes of RA+ILD Especially the SLAMF1, SLAMF2 and SLAMF7 expressing B cells can migrate to pulmonary and take part in the development of fibrosis and ILD, with the guide of chemokines. This indicated a joint-lung axis hypothesis might play important roles in the development and progression of RA-ILD.

DIPYRIDAMOLE, A COMPOUND THAT INCREASES EXTRACELLULAR ADENOSINE LEVELS, AS A THERAPEUTIC AGENT FOR RHEUMATOID SARCOPENIA

Keywords: Rheumatoid arthritis, Animal models, Sarcopenia

M. Marco-Bonilla1, M. Fresnadiillo1, I. Sanchez2, R. Largo3, G. Herrero-Beaumont1, A. Mediero1. 1IIS-Fundación Jiménez Díaz, Bone and Joint Metabolism, Madrid, Spain

Background: In addition to joint damage, rheumatoid arthritis (RA) confers a higher risk of several comorbidities, including changes in body composition with reduced muscle mass and strength (sarcopenia) with stable or increased fat mass. Adenosine and ATP are responsible for the maintenance of energy balance and activate cell signaling through selective receptors. Adenosine A2A receptor activation regulates bone turnover, targeting bone destruction in inflammatory diseases like RA. The use of dipyridamole (blocks adenosine uptake by the cells increasing extracellular adenosine levels activating adenosine receptors) modulates the intracellular and extracellular levels of adenosine and ATP in murine C2C12 myoblasts, via activation of the adenosine A2B receptor, cAMP and AMPK pathways, countering deleterious effects on skeletal muscle differentiation.

Objectives: To determine if dipyridamole prevents sarcopenia in arthritis murine model.

Methods: 12-wk-old C57BL/6 male mice were injected with pooled K/BxN serum (100 μl, ip) on day 0 and 2. Dipyridamole 25mg/Kg was administered daily starting after the first serum injection. Clinical signs (joint swelling and thickness) were measured daily. DXA analysis and motor activity tests were performed prior to serum inoculation and at day 13. Mice were euthanized on day 16. Inflammatory cytokines and C-reactive protein (CPR) were measured in serum. Gastronemius was collected for protein and RNA extraction. Tibialis was frozen and embedded in OCT for histology.

Results: Serum transfer (RA mice) induced an increase in joint inflammation that was maximal 2wk after injection. Dipyridamole decreased the appearance of inflammation in the joints (clinical score of 5±3 vs 14±1 RA mice, p<0.005, n=7), and counteracted weight loss (p<0.01). Moreover, dipyridamole modulates the systemic inflammation found in RA mice promoting an significant increase on anti-inflammatory cytokines such as IL-10, and a significant reduction on pro-inflammatory cytokines such as INFγ, IL-1, TNFα and IL-6, with a non significant decrease in CRP. In motor tests, the RA mice had a reduced distance traveled when compared to healthy mice (sham) (830±37cm vs 1393±187cm Sham, p<0.001, n=4-7), as well as a reduced strength (22.4±4.7g vs 44.4±3.9g Sham, p<0.05, n=4-7) and endurance, while the rotarod test showed a loss of motor coordination with increase of latency to fall (43.3±5.4sec vs 75.9±3.3sec Sham, n=0.05, n=4-7). Dipyridamole treatment resulted in a revertion of physical development induced by serum transfer. Furthermore, RA mice had decreased lean mass, BMD and BMC, as well as an increased fat percentage, that were reverted in the presence of dipyridamole. RA mice muscle weights decreased when compared to sham mice, whereas dipyridamole reversed this effect. MHC protein expression was decreased in RA mice when compared to sham mice (65±7% vs 100% Sham, p<0.005, n=4-7) and reverted by dipyridamole (84±6% vs 60±7%RA mice, p<0.005, n=6-7), meanwhile PAX7 expression was enhanced by dipyridamole (274±11% dipyridamole, 151±13% RA mice vs. 100%, p<0.005, n=6-7). AMPK activation decreased in RA mice (53±7% decreased vs Sham, p<0.05, n=4-7), whereas dipyridamole reversed this loss (152±5% dipyridamole vs 53±7% RA mice, p<0.001, n=6-7). Adenosine A2A and A2B receptors protein expression were decreased in RA mice (71±3% for A2A and 35±9% for A2B vs 100% Sham, p<0.005, n=4-7), been reverted by dipyridamole. Senescence markers p21 and p16 were increased in RA mice (221±38% for p21 and 392±25% for p16 vs 100% Sham, p<0.001, n=4-7) and dipyridamole reduced their expression.

Conclusion: Arthritic mice developed sarcopenia accompanied by a loss of motor activity, strong systemic inflammation and an increased muscle senescence. Dipyridamole counteracted both systemic and joint inflammation as well as muscle loss, enhancing muscle regeneration. This indicate that the use of agents that increase extracellular adenosine levels might be interesting as a therapeutic approach for inflammatory sarcopenia.

enrolling patient with RA and T2D, we demonstrated that IL-1 inhibition led to a marked reduction of glycated haemoglobin together with a decrease of RA disease activity [2].

**Objectives**: To evaluate the synovial expression of IL-1 related genes and the relationship to the ubiquitin-proteasome system in the synovial tissues of RA patients with and without T2D. To assess the effects of high concentration of insulin in vitro, mimicking the hyperinsulinaemia of the early phases of T2D, on ubiquitinated proteins in fibroblast-like synoviocytes (FLSs).

**Methods**: Early (-1 year) treatment-naïve RA patients with T2D (RA/T2D n=16) were compared with age- and gender-matched RA patients without T2D (n=16) enrolled in the Pathobiology of Early Arthritis Cohort (PEAC) [3]. Synovial tissue biopsies obtained under ultrasound guidance underwent RNA-sequencing as previously described [3], and we compared IL-1 pathway genes in patients without and with T2D. The synovial expression of ubiquitin in macrophages and synovial lining fibroblasts was assessed by immunohistochemistry/immunofluorescence and correlated with synovial pathotypes [4]. Finally, FLSs from RA patients (n=5) were isolated and treated with human insulin (200 and 500 nM) for 7 days, and ubiquitinated proteins were assessed by western blot.

**Results**: Synovial RNA-sequencing showed that one third of IL-1 pathway genes (41/138) were significantly different in RA/T2D patients compared to RA patients without T2D. In parallel, synovial tissues of RA/T2D patients were characterised by a consistent reduced expression of ubiquitin-proteasome genes. More specifically, ubiquitin genes (UBB, UBC, and UBA52) were significantly lower in T2D/RA patients. Furthermore, 22 genes coding proteasome subunits were significantly lower in RA/T2D patients (PSMA2, PSMA6, PSMA7, PSMB1, PSMB3, PSMB4, PSMB6, PSMB7, PSMB9, PSMB10, PSMC1, PSMC3, PSMC5, PSMC13, PSMD4, PSMD7, PSMD8, PSMD9, PSIEM1, PSME2, and PSMF1). Additionally, several genes regulating ubiquitin and proteasome system were significantly different in the synovial tissue of RA/T2D patients. Specifically, APP, BAG4, and BTRC were upregulated in RA/T2D patients. Conversely, RACK1, RBX1, RPS27A, SEM1, SHARPIN, and SIGIRR were significantly downregulated in RA/T2D patients. Immunohistochemistry showed a significant reduction of the percentage of ubiquitin-positive cells in synovial tissues of RA/T2D patients. The percentage of ubiquitin-positive cells was also increased in patients with a lympho-myeloid pathotype compared to diffuse myeloid or pannus-immune fibroblast. Despite its widespread expression in synovia, immunofluorescence showed that ubiquitin mainly colocalized with synovial macrophages and lining fibroblasts. Finally, in vitro experiments showed a reduction of ubiquitinated proteins in RA-FLSs treated with a high concentration of insulin (500 nM).

**Conclusion**: Increased IL-1 gene expression was observed in the synovial tissues of RA/T2D patients, both during baseline and concomitant comorbidity T2D, as the reduction of the ubiquitin-proteasome system may enhance the levels of IL-1. These findings may provide a mechanistic explanation of the observed clinical benefits of IL-1 inhibition in patients with RA and concomitant comorbid T2D.

**Disclosure of Interests**: None Declared.

**HIGH THROUGHPUT MULTIPLEX PROTEOMICS IDENTIFIES BIOMARKERS AND NETWORKS ASSOCIATED WITH THE RHEUMATOID ARTHRITIS-CARDIOVASCULAR DISEASE (RA-CVD) MULTIMORBID AXIS**

**Keywords**: Rheumatoid arthritis, Cardiovascular disease, Biomarkers

**Background**: Rheumatoid arthritis (RA) patients have higher mortality rates compared to the general population, primarily due to excess cardiovascular (CV) disease (CVD). We have shown the earliest stages of RA are associated with CV abnormalities but blood biomarkers to identify CVD in early RA are lacking.

**Objectives**: In a treatment-naïve new-onset RA trial cohort, to identify (i) blood-based protein biomarkers that associate with cardiovascular magnetic resonance imaging (CMR) abnormalities, (ii) whether these biomarkers are sensitive to change; (iii) the predominant inflammatory and metabolic pathways implicated.

**Methods**: CADERA (Coronary Artery Disease in Early RA)[1] was an add-on study to a parent RCT of an early RA inception cohort where 81 patients underwent CMR at baseline and year 1. Proximity extension immunoassay (Olink®-based) was used to measure normalised protein expression (NPX) across inflammation, CV II/III and cardiometabolic panels at time of CMR. Bayesian linear mixed effects regression was used to identify proteins associated with CMR parameters of myocardial oedema/fibrosis (MO/ MF = native T1, myocardial extracellular volume (ECV) and late gadolinium enhancement (LGE)) and vascular stiffness (VS = aortic distensibility and stiffness index) at baseline, year 1 and those sensitive to change over time. An expanded protein interaction (PPI) network using baseline proteins was created using an induced network approach (String-DB) and clusters identified using k-means that were then subjected to Gene ontology (GO) and KEGG enrichment analysis.

**Results**: Of 340 proteins analysed using Olink, 108 proteins were associated with CMR markers of MO/MF (64 proteins; 28 positively, 36 negatively) and VS (44 proteins; 13 positively, 38 negatively) at baseline. 46/108 proteins identified at baseline were sensitive to change over time and of these, 15 remained associated with CMR parameters at Year 1 (see Figure 1A & B). No overlapping proteins were identified that associated with focal (LGE) and diffuse fibrosis (ECV). Table 1 reports posterior estimates and 95% credible intervals for two top proteins. Figure 1C displays changes in predicted NPX for 2 time-sensitive proteins associated longitudinally with CMR parameters. K-means clustering of the expanded baseline PPI network (enrichment p < 0.0001) identified 4 clusters (Figure 1D) with roles in IL27 receptor binding and NF-kB signalling pathway (red), vascular endothelial growth factor receptor binding and JAK-STAT signalling pathway (green); Macrophage CSF receptor binding and ErBb signalling pathway (blue); and IL-1 receptor activity and complement and coagulation cascades (yellow).

**Conclusion**: This is the first study to identify sensitive protein biomarkers that may help with early diagnosis and monitoring of RA-CVD and inform on possible therapeutic targets. Treatment group differences and subgroup analyses with responders are ongoing. Further validation of these candidate biomarkers is needed in an independent cohort.

**Disclosure of Interests**: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.4048
Background: CD38 is a NAD+ consuming enzyme ubiquitously expressed on immune cells and its expression increases in several pathological conditions, including Rheumatoid Arthritis (RA) [1, 2]. Pre-clinical studies in CD38 knock-out models have demonstrated that CD38 deficient animals develop an attenuated form of Collagen-Induced-Arthritis (CIA) characterized by reduced inflammation and damage at the joint level suggesting a causal role of CD38 in the pathogenesis of CIA and, potentially, RA [3-5].

Objectives: This study investigated the efficacy of NTX-748, a newly developed, potent and orally available small molecule inhibiting the enzymatic activity of CD38, in reducing the inflammation, cartilage destruction, pannus formation, and damage at the joint level in CIA rat model for the study of RA.

Methods: Mice were injected intradermally (ID) with Freund’s complete adjuvant (CFA) containing bovine type II collagen to induce arthritis on study days 0 and 21. Beginning on study day 18, the animals were dosed twice daily (BID) by the oral route (PO) with vehicle or NTX-748 (3, 10, or 30mg/kg), or DPO once daily (QD) with Methotrexate (1mg/kg) (n=12/group) for 18 days. One group served as a mal model for the study of RA.

Results: Treatment with NTX-748 at 10 and 30mg/kg showed a statistically significant dose-dependent beneficial effect reducing day 36 CAS by 37% and 50% respectively relative to vehicle (p=0.13 and p=0.047), without showing any toxicity, including body and spleen weights. Histopathology analysis of joints, paws and knees confirmed NTX-748 efficacy. Strikingly, NTX-748 reduces incidence of CAS up to 50% in a dose-dependent manner (p = 0.0015). Plasma concentrations of NTX-748 increased approximately in proportion to dose. Mass Spectrometry-based tissue metabolic analysis (liver and spleen) confirmed target engagement with dose dependent increases of NAD+ levels, the main substrate of CD38-mediated NAD+ hydrolysis, and decreases of NAM and ADPR, both engaged with dose dependent increases of NAD+ levels, the main substrate of CD38-mediated NAD+ hydrolysis, and decreases of NAM and ADPR, both products of the same enzymatic reaction. Methotrexate 1mg/kg also demonstrated efficacy (98% reduction in CAS) however significant splenomegaly (3-fold increase) indicated toxicity at this dose.

Conclusion: Our results demonstrated that NTX-748, a small molecule inhibiting the NADase enzymatic activity of CD38, is efficacious in the mouse CIA model, and thus potentially RA. These data confirm the potential of CD38 as druggable target in the treatment of inflammation-driven autoimmune diseases such as RA.

DOI: 10.1136/annrheumdis-2023-eular.5084
Objectives: To evaluate the effect of tofacitinib on muscle mass of collagen-induced arthritis (CIA) mice.

Methods: CIA was induced in male DBA/1J mice. Animals were randomized into 3 groups: I) CIA + tofacitinib (CIA-TOF; n=10); II) CIA + vehicle (CIA-VEH; n=10); III) healthy controls (CO; n=9). Vehicle (PBS) or tofacitinib 15mg/kg were administered twice a day, between days 18 and 45 after the disease induction. Clinical score, edema and body weight were evaluated during the experimental period. After euthanasia, tibio-tarsal joints were collected for assessment of disease histopathological score, and tibialis anterior (TA) and gastrocnemius (GA) muscles were weighed to assess muscle mass. Muscle atrophy was evaluated by measurement of TA myofiber cross-sectional area (CSA). Expression of proteins related to muscle regeneration or catabolism (Pax7, MyoD, myogenin and Murf-1) were evaluated by western blot in GA homogenates. Serum inflammatory markers (TNF and IL-6) were evaluated by ELISA. Statistical analysis included ANOVA followed by Tukey’s or with Kruskal-Wallis. The statistical difference was assumed for p<0.05.

Results: As expected, tofacitinib treatment decreased arthritis severity by reducing clinical score (p=0.03) and hind paw edema (p=0.04) in comparison with CIA-VEH group. CIA-TOF showed weight gain (p=0.02), higher TA (p=0.009) and GA (p=0.02) weights, and increased CSA compared to CIA-VEH group (p=0.01). On day 45, CIA-TOF presented increased muscle strength compared to CIA-VEH group (p=0.006), however, no difference was found in the fatigue parameter among groups (p=0.05). The expression of Pax7 was unchanged (p=0.07), while MyoD expression showed an increase trend, and myogenin expression was significantly increased in CIA-TOF compared to CIA-VEH (p=0.04) and CO groups (p=0.02). The treatment did not significantly modify Muf-1 expression. Compared to CIA-VEH group, CIA-TOF mice showed decreased serum levels of TNF (p=0.04), and no difference in IL-6 serum levels (p=0.08).

Conclusion: Tofacitinib attenuated muscle loss in arthritic mice, as increased muscle weight and muscle CSA were detected in treated mice. Additionally, an increased activation of satellite cells regeneration, based on the expression of myogenin, is a potential mechanism involved in tofacitinib-protection against muscle loss.

Background: Activated monocytes play a key role in the initiation and progression of inflammatory synovitis in rheumatoid arthritis (RA), leading to cartilage destruction and, via invasive pannus development, loss of peri-articular bone.

Objectives: To test the efficacy of an orally administered functionally selective immunomodulator in a murine collagen-induced arthritis (CIA) model.

Methods: Mice were immunized with collagen type II and treated with the immunomodulator or vehicle. Clinical scores, paw swelling, and joint histology were assessed. Overall, the immunomodulator demonstrated significant efficacy in reducing clinical scores and paw swelling.

Results: The immunomodulator significantly reduced clinical scores and paw swelling compared to the control group. Histological analysis showed decreased synovitis and cartilage erosion in the treated group.

Conclusion: The immunomodulator showed promise in reducing inflammation and preserving joint integrity in a murine CIA model.

DOI: 10.1136/annrheumdis-2023-eular.532
ER000145 is a functionally selective immunomodulator derived from IT1t, a CXCR4 antagonist demonstrated to exert immunomodulating proper-
ties[1]. As an immunomodulating model compound, ER000145 previously 
showed increased potency by downmodulating several key pro-inflammato-
tory cytokines in Toll-like receptor (TLR)7/8-stimulated immune cells and 
low/no CXCR4 antagonism in vitro as well as strong efficacy in a murine 
pristane-induced lupus model[2].

Objectives: The aim of the present study is to evaluate the potency of the 
functionally selective immunomodulator ER000145, both 
in vitro on murine and human 
immune cells as well as in vivo in a murine collagen-induced arthritis 
(mCIA) model.

Methods: In vitro 
immunomodulating potency of ER000145 was evaluated in fresh murine 
splenocytes and isolated primary monocytes from healthy volun-
tees (HV). After 1-hour incubation with ER000145 and 24-hour stimulation with 
TLR7/8 agonists (R848 or RB37, 5 or 1 µg/mL respectively), supernatant was 
collected. Pro-inflammatory cytokines were detected by flow cytometry (Legend-
plex). For the mCIA model, male DBA-1 mice (n=8 per group) were 
immunized with bovine collagen type 2 on Day 1 in Complete Freund Adjuvant 
(FA) and on Day 21 with Incomplete FA. Mice were randomized and dosed 
once daily (QD) intraperitoneally (IP) with either PBS (vehicle control), 
ER000145 at 3, 10 or 30 mg/kg, or IT1 at 30 mg/kg as of Day 28, for 
a duration of 14 days. As a positive control, mice received 10 mg/kg predni-
solone QD orally. Blood samples were collected after single (Day 28) and 
14-days of repeated dosing to evaluate exposure of ER000145. During the 
study, disease activity was monitored on the basis of the extent of edema and 
erythema in each paw, and paw thickness was measured using a digital 
caliper. At study termination, all paws from the vehicle-treated and 30 mg/kg 
ER000145-treated mice were collected and prepared for histopathological 
scoring using hematoxylin and eosin (H&E) staining.

Results: ER000145 inhibited key pro-inflammatory cytokines (TNF-α/IL-6/IL-1β) 
in TLR7/8 agonist-stimulated HV primary monocytes as well as murine sple-
ocytes. Daily IP administration of ER000145 in a mCIA model reduced significantly 
clinical scores in a dose-dependent manner: a dose of 3 mg/kg was not effica-
cious in contrast to both the 10 and 30 mg/kg QD doses. At efficacious doses, 
the average concentration (Cavg) of ER000145 in blood ranged between 14 and 
31 ng/mL, indicating that the lipid profile is more predictive of the disease activity 
in both groups. Univariate analysis highlighted relatively higher concentration of 
large density HDL subclasses (HDL-4 Cholesterol (p=0.003), ApoA1 (p=0.0003), 
ApoA2 (p=0.0018) and Phospholipids (p=0.0024), Sphingomyelin (SM[24:0]; 
p=0.0012), Hexosylceramide (HCER[22:0]; p=0.0557), and Cholesterol Esters 
(CE[18:0]; p=0.0025, CE[18:2]; p=0.0721), but lower Glycoproteins A and B 
(p=0.0003; 0.0007) levels in Remission. RA patients in remission were characterized by high levels 
of LDL (LDPN, L4PN), HDL Apolipoprotein A1 (HDA1, H4A1), Cholesterol Esters 
(CE[18:2], CE[18:1]) and Phosphatidylcholines (PC[16:0/20:4), PC[18:0/20:4]) compared 
to those in remission. RA patients in remission were characterized by high levels 
of LDL (LDPN, L4PN), HDL Apolipoprotein A1 (HDA1, H4A1), Cholesterol Esters 
(CE[18:2], CE[18:1]) and Phosphatidylcholines (PC[16:0/20:4), PC[18:0/20:4]).

Conclusion: In summary, comprehensive lipoprotein and lipid analysis identi-
ifies markers that characterize RA in exacerbation and remission. Large density 
HDL-4 Apolipoprotein A1 and Cholesterol Esters are indicative of Remission, 
while VLDL, Triglycerides and Free fatty acids describe High disease activity in 
RA. The above markers will be evaluated in comparison with those already exist-
ning in clinical laboratory application.

Background: Since the discovery of the sphingosine-1-phosphate (S1P) pathway and its potentially beneficial role of inducing lymphocyte retention and subsequent immunomodulation [1], several small molecule S1P receptor modulators have been approved for the treatment of diverse autoimmune diseases such as multiple sclerosis and ulcerative colitis. Cenerimod, a selective S1P receptor modulator, has shown efficacy in preclinical models of systemic lupus erythematosus (SLE), systemic sclerosis and Sjögren’s syndrome [2-4] and is now entered into a Phase III clinical trial (OPUS; NCT05648500) in patients to moderate to severe SLE.

Objectives: We investigated the efficacy of cenerimod in modulating disease progression in preclinical models of rheumatoid arthritis (RA).

Methods: We analyzed the efficacy of cenerimod in several models of RA in mice and rats. Disease-relevant biomarkers such as autoantibody development and chemokine secretion were measured to gain a deeper understanding of the mode of action of S1P receptor modulation in these RA models.

Results: In mouse RA models, prophylactic treatment with cenerimod inhibited the acute inflammatory response post antigen challenge and prevented autoantibody formation, thus completely preventing the initiation of disease. Cenerimod treatment at disease onset further showed a strong reduction of joint inflammation and significantly delayed clinical symptoms and the secretion of several pro-inflammatory chemokines. Although corticosteroid treatment is frequently administered as an adjunct treatment for interventional strategies. However, this currently requires invasive synovial tissue sampling. Novel whole-body molecular imaging with positron emission tomography (PET) and the use of specific PET tracers can non-invasively detect and quantify the presence of immune cells in RA inflamed synovium. Folate-receptor beta (FRβ) is a cell surface receptor on macrophages, shown clinical exploitation for high specificity PET imaging of arthritis [2]. However, it remains to be elucidated whether FRβ is a suitable marker for RA immunopathotype stratification. Furthermore, it is unclear whether FRβ is expressed on macrophages with a pro-inflammatory (M1) or homeostatic (M2) phenotype in the 3 immunopathotypes.

OBJECTIVES: (1) Investigate FRβ expression across the three distinct RA immunopathotypes.
(2) Investigate FRβ expression in relation to the general macrophage marker CD68 and the mannose receptor CD206 (which is associated with M2-type macrophages [3]).

Methods: Synovial biopsies of the RA-affected ankle or knee (N=28) were retrieved from RA patients with clinically active disease defined by ACR RA criteria [4]. Subsequently, biopsy sections were immunohistochemically stained in order to stratify each patient into one of three RA-immunopathotypes. Confocal microscopy was used to determine CD68, FRβ and CD206 expression (integrated density), and co-expression (comparing fold-change average expression) for all patients within each immunopathotype (N=8-10/group).

Results: Out of 28 RA synovial biopsies 10 could be classified as FP, 9 DM and 9 LM immunopathotype. Average expression of CD68, FRβ and CD206 was significantly increased in the DM and LM compared to the FP immunopathotype (# p<0.01). Quantitative CD68, FRβ and CD206 expression was highest in the DM immunopathotype. FRβ expression correlated significantly with CD206 expression in all three pathotypes (Spearman R_{p}=0.67, P_{corr}=0.76; R_{p}=0.49). On the contrary FRβ expression did not correlate with CD68 expression except in the DM pathotype (Spearman R_{p}=0.46).

Conclusions: The results of this study put forward that FRβ is a potential target for delineation of RA immunopathotypes, to be explored for non-invasive molecular imaging stratification. Furthermore, investigation of FRβ expression has an additive value over CD68 since it can be used to distinguish the presence of M2 macrophages in the RA synovium specifically.

Background: Rheumatoid Arthritis-associated Interstitial Lung Disease (RA-ILD) is an extraarticular manifestation with clear clinical relevance because it impairs quality of life and survival. Despite this, RA-ILD etiology and pathogenesis are only partially understood. However, we know that fibrosis and collagen deposition, aging and telomere shortening, the expression of the mucin MUC5B gene, the RA autoantibodies and smoking are contributing elements. A better knowledge of RA-ILD pathogenesis will lead to improved outcomes for the patients.

Objectives: This study aims to identify CpG sites that are differentially methylated in the blood of RA-ILD patients compared to matched RA patients without ILD. These findings will point to genes and pathways of specific relevance to RA-ILD pathogenesis.

Methods: We compared two matched groups of 32 patients with RA: RA patients diagnosed with ILD less than one year before sample collection; RA patients without ILD. The two groups were assessed by High-Resolution Computed Tomography (HRCT) and matched by sex, age, smoking (ever/never), and anti-CCP status. Blood samples were used for DNA extraction. Methylation of 850000 CpG was measured with the Infinium Methylation Epic BeadChip (Illumina). Identification of the differentially methylated positions (DMP) and differentially methylated regions (DMR) was performed using the R application ShinyEPICO [1]. Gene set enrichment analysis (GSEA) was done with the R package methyGSA [2].

Results: A total of 6679 DMP with ≥ 2% difference and FDR < 0.05 were identified in the autosomal chromosomes. In addition, 119 DMR (72 in gene bodies, 32 in promoters, and 15 in CpG islands) were discovered. Some of these DMP and DMR are associated with genes of known relevance (Figure 1): genes involved in telomere maintenance (TERC, TERT, POT1), and some genes related to immunological processes (HLA-DRA, VCAM1, TGFB2...). A systematic analysis of the associated genes with GSEA showed significant enrichment of 62 gene ontology (GO) terms and 49 Reactome pathways. Several of the top enriched GO terms referred to the detection of chemical stimuli involved in sensory perception, either by smell or taste. This finding was replicated in the enriched pathways. Other top GO terms identified chromosome changes during mitosis: centromeric duplication, chromosome segregation, and others. They corresponded to top-enriched pathways involved in the M phase of mitosis and cell cycle checkpoints. Another group of GO terms referred to post-translational modifications of proteins: deacylation of proteins, which coincided with top pathways involved in protein modifications, including acetylation and deacetylation of histones; and ubiquitination of proteins, also reflected in several top enriched pathways. Besides, enriched GO terms that referred to the catabolic process of nuclear-transcribed mRNA correlated with top pathways of mRNA metabolism. In addition, there were other significantly enriched gene sets, such as the involved in the transport of intracellular vesicles and the location in the cell of proteins, mitochondria, RNA, and chromosomes, the host interaction with viral infections, gene silencing by small RNA, SUMOylation, and the RHO GTPase cycle.

Conclusion: We observed significant differences in blood DNA methylation between matched RA-ILD and RA-control patients. Some of these differences were related to potentially interesting genes (mucins, collagen, telomere maintenance), and biological processes and pathways (detecting chemical stimuli, post-translational modifications of proteins, chromosome and intracellular vesicle localization, and transport) that will help us to better understand RA-ILD pathogenesis.

Figure 1. Violin plots of DNA methylation β values of individual CpG sites annotated to the selected genes comparing RA-ILD and RA control groups. X axis is in the log10 scale (M values).
Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that leads to progressive joint destruction involving multiple joints. There is a large body of evidence that suggests a crucial role for activated synovial fibroblasts (RASF) in mediating both direct tissue injury and perpetuation of the complex disease process in RA [1]. RA SF from RA patients are able to attach to articular cartilage and deeply invade and degrade the cartilage matrix [2] and have been shown to migrate to secondary joint locations in vivo and invade and degrade cartilage similarly to the primary site [3]. Human gingival-derived mesenchymal stem cells (GMSC) are promising therapeutic cell treatments for autoimmune diseases due to their immunomodulatory capacity [4]. Others have demonstrated the ability of GMSC to home to the site of the implant and induce programmed cell death of the RASF through the direct transfer of exosomes [5]. Objectives: Our aim was to test whether the deleterious effects of RASF in an in vivo chimeric mouse model of RA could be modulated by the presence of GMSC or GMSCExo. In addition, we analyzed the effects of both GMSC and GMSCExo on the ability of RASF to migrate to secondary locations. Mechanistic studies were done to understand how GMSC and GMSCExo inhibited the GMSC-mediated invasiveness of the RASF. Methods: A chimeric human/mouse model of synovitis was created by surgically implanting SCID mice with a small piece of human articular cartilage surrounded by RASF. Each mouse received two implants; the primary implant on the right flank of the mouse contained RASF, the secondary implant contained no RASF. Mice were retro-orbitally injected once with either GMSC or GMSCExo at 5-7 days post-implantation. The implants were removed after 60 days for evaluation. Histology and IHC were used to assess RASF invasion of the cartilage. Flow cytometry was used to understand the homing ability of GMSC in vivo, the incidence of apoptosis of RASF and the exchange of exosomes in vitro. Results: We demonstrate that both GMSC and GMSCExo are potent inhibitors of the deleterious effects of RASF. Both treatments were effective in inhibiting the invasive destructive properties of RASF as well as the potential of these cells to migrate to secondary locations and attack the cartilage there. We also present evidence that GMSC home to the site of the implant and induce programmed cell death of the RASF through the direct transfer of exosomes. Conclusion: Our results indicate that both GMSC and GMSCExo can block the pathological effects of RASF in this chimeric model of RA. A single dose of either GMSC or GMSCExo can inhibit the deleterious effects of RASF. These treatments can also block the invasive migration of the RASF, suggesting that they can inhibit the spread of RA to other joints. Because the gingival tissue is harvested with little difficulty, relatively small amounts of tissue are required to expand the cells, they are simply in vitro expansion process, and the increasing technological advances in the production of therapeutic exosomes, we believe that GMSCExo are excellent candidates as a potential therapeutic agent for RA. Rheumatoid arthritis (RA) results from a gene-environment interaction and is characterized by a preclinical, or asymptomatic, phase during which autoimmune processes appear, in particular anti-citrullinated protein antibodies (ACPA) [1]. This gene-environment interaction, occurs many years before the diagnosis of RA, possibly during childhood. Only smoking, in genetically predisposed patients (carriers of the shared HLA-DRB1 epitope), has been shown to be a reproducible risk factor for developing seropositive RA [2,3]. Other inhaled substances may play a role as many non-smokers develop RA, inducing inflammation of the lung mucosa and a systemic immune response, such as occupational exposure to silica, possibly pesticides and air pollution [4]. Early life exposures may play a major role in the pathophysiology of RA. All these elements lead us to study the impact of exposure to environmental factors in childhood on the risk of RA in adulthood, mainly airborne exposure.

**Objectives:** To assess the relationships between exposure to a rural lifestyle during childhood and the risk of RA in women involved in the E3N cohort.

**Methods:** E3N is an ongoing French prospective cohort that included 98,995 women aged 40-69 years. Women completed, every 2-3 years, mailed questionnaires about their lifestyle and health-related information. In 2002 a questionnaire about their childhood environment was assessed, including passive smoking, educational level, smoking during pregnancy and World War II deprivation scores, exposure to cats and dogs at home, whether women had lived on a farm for at least 3 successive months during childhood, and if so, the type of animals they were exposed to and their age at first pet or farm animal exposure. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using multi-adjusted Cox proportional hazards regression models with age as the time scale.

**Results:** A total of 657 incident RA cases, among whom 77,754 non RA women were ascertained. Farming lifestyle was not associated with the risk of RA. In contrast, in a multi-variable-adjusted Cox regression model including known risk factors of RA (age, active and/or passive smoking during adulthood, BMI, educational level), exposure to cats and/or dog between 1 and 2 years old was associated with a decrease risk of incident RA compared to children without pets: HR = 0.55 (95% CI 0.3-0.9), p= 0.031. Furthermore, as previously described, passive smoking in childhood [HR=1.24 (1.0-1.5)] was associated with the risk of smoking during pregnancy and World War II deprivation scores, exposures to cats and dogs at home, whether women had lived on a farm for at least 3 successive months during childhood, and if so, the type of animals they were exposed to and their age at first pet or farm animal exposure. Risk ratio (RRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using multi-adjusted Cox proportional hazards regression models with age as the time scale.

**Conclusions:** More than farming lifestyle or the type of pet, the very early exposure to cats and/or dog (1-2 years) seems to reduce the incidence of RA while passive smoking in childhood increases it. This supports the idea that the lung environment during pregnancy and World War II deprivation scores, exposures to cats and dogs at home, whether women had lived on a farm for at least 3 successive months during childhood, and if so, the type of animals they were exposed to and their age at first pet or farm animal exposure. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using multi-adjusted Cox regression models with age as the time scale.

**Background:** Rheumatoid arthritis (RA) patients are heterogeneity in their clinical phenotype and in response to molecular targeted therapies. To date, only limited number of studies addressed the immunological changes that lie behind the clinical heterogeneity.

**Objectives:** To identify immunological correlates of clinical phenotypes and predictors of treatment response, we performed peripheral blood multi-omics profiling of patients initiating abatacept treatment.

**Methods:** In the PREDICTABA study, we have recruited 104 RA patients starting abatacept treatment at six hospitals in Japan (Figure 1A). Peripheral blood mass cytometry analysis was performed in discovery and validation cohorts (n=79 and 22). In total, 10 million T and B cells were clustered by cell surface protein expression (Figure 1B, 1C). After accounting for the effects of age, sex, CD43 assay activity, anti-CCP antibody status, and cluster status, the impact of baseline treatment and future abatacept treatment response (CDAI improvement at 6 months) using mixed-effects modeling of association of single cells [1]. Peripheral blood RNA-seq identified immune cell signatures and immune pathway signatures.

**Results:** At baseline, median age was 73 years, 80% were female and 80% were seropositive. Median CDAI improved from 17 to 5 after 6 months of abatacept treatment. RNA-seq immune cell gene signatures validated mass cytometry immune cell cluster frequencies. Naïve CD T cells were negatively associated with baseline prednisone use (OR 0.53 and 0.25, P-values <0.01). Plasmablasts were negatively associated with baseline methylxerate use (OR 0.59 and P-value<0.01, Figure 1B, 1D, 1E), and with IL6, IL8, STAT3 signaling gene signature (P-value<0.01). Finally, CD8+CD25+ T cells showed suggestive association with CDAI improvement after abatacept treatment (OR 1.4 and 1.6, P-values 0.01 and 0.07, Figure 1C, 1F, 1G).

**Conclusion:** Through immunophenotyping analysis of RA patients, we have revealed that B cell subsets are associated with conventional RA treatments. Abundance of CD8+CD25+ T cells may be predictive of good abatacept response.

FOCAL ADHESION PROTEINS KINDLIN-1, -2 AND TALIN-1 ARE REGULATED IN IL-1ß-STIMULATED RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

Keywords: Synovium, Cytokines and chemokines, Rheumatoid arthritis

M. Arnold1, S. Reharts2, M. Sauerbier3, C. Biehl4, C. Heck5, U. Müller-Ladner6, E. Neumann7. 1Justus-Liebig-University, Campus Klinikum, Department of Rheumatology and Clinical Immunology, Bad Kissingen, Germany; 2Agapeologie Markers University, Department of Genetics and Trauma Surgery, Frankfurt, Germany; 3Private Practice for Hand and Plastic Surgery, Frankfurt, Germany; 4Private Practice for Hand and Plastic Surgery, Bad Homburg v. d. Hoehe, Germany; 5University Hospital of Giessen-Marburg, Dept. of Trauma, Hand and Reconstructive Surgery, Giessen, Germany.

Background: Rheumatoid arthritis (RA) is a progressive chronic inflammatory autoimmune disease characterized by synovial hyperplasia, articular inflammation and excessive joint and bone erosion. Activated RA synovial fibroblasts (SF) are key players of cartilage erosion by attaching and invading into cartilage. The kindlin family of focal adhesion proteins consists of six members, whose function is to activate integrins and thereby enable focal adhesion. Integrins play a central role in regulating cell-matrix and cell-cell adhesion. The effects of integrin activation are key players of cartilage erosion by attaching and invading into cartilage. Kindlin-1 and -3 were neither detectable in the cell body without a nuclear signal. Kindlin-1 and -3 were neither detectable in synovial tissue nor in synovial fibroblasts. Relative mRNA levels (arbitrary units) of kindlin-1, -2, -3 and talin-1 in RA synovial tissue and RA SF, and the impact of pro-inflammatory activation on their expression on mRNA and protein level.

Methods: Synovial fibroblasts were isolated from synovial tissue after joint replacement surgery. Cells were cocultured in the presence of IL-1ß (10 ng/ml), T cell antigen-presenting cells (anti-CD40 and 1 ng/ml IL-21), or NIKi (12.5 µM NIKi: 12.13±19.42% decrease; 25 µM IKKi: 6.90±5.38% decrease, 25 µM NIKi: 26.63±17.37% decrease, 50 µM NIKi: 41.69±2.00% decrease; data normalised on DMSO) upon T cell-dependent stimulation with 2.25 µg/ml anti-CD40 and 1.0 ng/ml IL-21 (Figure 1B). We observed a dose-dependent induction of IL-6 (49.1%) after repetitive IL-1ß exposure.

Results: In RA synovial tissues, kindlin-2 and talin-1 protein were detectable adjacent to blood vessels, in the synovial lining layer and in the sublining. Kindlin-2 and talin-1 could be detected in cultured RASF with a consistent signal of the cell body without a nuclear signal. Kindlin-1 and -3 were neither detectable in synovial tissue nor in synovial fibroblasts. Relative mRNA levels (arbitrary units) of kindlin-1 and kindlin-1 in RASF differed, with the strongest signal for kindlin-1 (1663 ± 186, followed by kindlin-2 (28 ± 23), kindlin-1 (2 ± 0.08) and kindlin-3 (0 ± 0.08). In contrast, repetitive stimulation doubled the signal of IL-1ß-stimulated RASF with IL-1ß (1-2-fold) after 17h and returned to the baseline levels after 48h. A time-dependent effect could also be observed by immunocytochemistry of IL-1ß-stimulated RASF. Kindlin-1 mRNA expression was significantly upregulated after 6h (2.9-fold, p=0.0178) of stimulation and downregulated after 17h (1-5-fold, p<0.0001), 24h (1-5-fold, p<0.0001) and 48h (1-2-fold, p<0.0001) compared to 6h. At后悔, repetitive activation of RASF, kindlin-1 and talin-1 were constantly regulated compared to the first stimulation (kindlin-1: 1.03-fold; kindlin-2: -1.06-fold; talin-1: 1.00-fold). In contrast, IL-6 showed an inflammatory adjustment to IL-1ß leading to lower induction of IL-8 (49.1%) after repetitive IL-1ß-exposure. Conclusion: Focal adhesion proteins kindlin-2 and talin-1, factors involved in integrin activation of cells, are present in RA synovial tissue and RASF. As a time-dependent regulation of kindlin-2 and talin-1 after stimulation was observed, this effect may lead to a temporary and repetitive productive activation of RASF and activation of integrins, subsequently contributing to altered adhesion and migration of RASF under inflammatory arthritic conditions. NF-KB SIGNALLING IS CRITICALLY IMPORTANT FOR FUNCTIONAL RESPONSES OF ACAP-PRODUCING B CELL CLONES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cell biology

G. Frenzel1,2, Y. Kan1,2, J. P. Van Hamburg1,2, R. Van Vollenhoven1, S. Tas1,2. 1Amsterdam Rheumatology Center, Amsterdam University Medical Centers, University of Amsterdam, Department of Clinical Immunology, Amsterdam, Netherlands; 2Amsterdam University Medical Centers, University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands.

Background: Anti-citrullinated protein antibodies (ACPA) play a role in rheumatoid arthritis (RA) pathogenesis, and their presence is associated with disease severity. Moreover, high serum levels of ACPA in the preclinical phase are one of the major risk factors for RA progression. Consequently, detailed analysis of ACPA+ B cells is required to disentangle the role of these cells in RA. Multiple intracellular signalling pathways are involved in functional responses of ACPA+ B cells. We make use of ACPA+ and ACPA- B cell clones, since peripheral ACPA+ cells are present at low frequencies in the peripheral blood.

Objectives: To identify whether NF-κB or JAK-STAT signalling inhibition using small molecule inhibitors (SMIs) is effective in targeting functional responses of ACPA+ B cells from RA patients, including survival, proliferation, differentiation, and antibody production.

Methods: Previously generated ACPA+ and ACPA- B cell clones [1] (see Figure 1A for method) were expanded and cultured with anti-CD40 and IL-21. Canonical and non-canonical NF-κB signalling were targeted by validated SMIs of Inhibitor of κB kinase (IKK), (canonical NF-κB signalling) and NF-κB inducing kinase (NIK), (non-canonical NF-κB signalling), respectively. Tofacitinib (a JAK1/JAK3 specific small molecule inhibitor) was used to target JAK-STAT signalling. Cell viability, proliferation and differentiation were evaluated by flow cytometry. Antibody production was measured by ELISA.

Results: We observed a dose-dependent reduction in proliferation in ACPA-producing B cell clones treated with either IKKi (12.5 µM IKKi: 39.12±9.86% decrease, 25 µM IKKi: 56.55±18.44% decrease, 50 µM IKKi: 65.65±3.1% decrease; data normalised on DMSO) or NIKi (12.5 µM NIKi: 12.13±19.42% decrease, 25 µM NIKi: 26.63±17.37% decrease, 50 µM NIKi: 41.69±2.00% decrease; data normalised on DMSO) upon T cell-dependent stimulation with 2.25 µg/ml anti-CD40 and 1.0 ng/ml IL-21 (Figure 1B). Similarly, we observed a dose-dependent reduction in IgG production (Figure 1C). IKKi treatment seemed to have a stronger effect than NIKi treatment on ACPA+ B cell clones, while we did not observe a clear difference between IKKi and NIKi in ACPA+ B cells (12.5 µM IKKi: 6.90±5.38% decrease, 25 µM IKKi: 33.32±2.15% decrease, 50 µM IKKi: 50.11±3.15% decrease, 12.5 µM NIKi: 6.90±3.61% decrease, 25 µM NIKi: 17.83±6.53% decrease, 50 µM NIKi: 54.67±20.37% decrease; data normalised on DMSO). These effects were not caused by cytotoxic effects as cell viability was not affected by IKKi or NIKi treatment. In contrast to the effects of IKK and NIKi treatment, tofacitinib only had limited effects on ACPA+ and ACPA- B cell proliferation and IgG production. At present these results are being corroborated by using freshly isolated ACPA+ B lineage cells of RA patients.

Conclusion: Our data point towards a critical role of the NF-κB signalling pathways in the functional responses of ACPA-producing B cells, whereas a limited role of JAK-STAT signalling was observed. Consequently, targeting NF-κB signalling may have beneficial effects in limiting (auto)reactive B cell responses in RA.

Background: The gut microbiota has been proposed to be an important environmental factor in the development of rheumatoid arthritis (RA). However, changes in the gut microbiome of RA patients who were already treated with disease-modifying anti-rheumatic drugs (DMARDs) have not been studied well.

Objectives: We aimed to investigate the gut microbiota of patients with established rheumatoid arthritis (RA) who have been managed with DMARDs for a long time. We focused on factors that might affect composition of the gut microbiota. Furthermore, we investigated whether gut microbiota composition predicts future clinical responses to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) in patients with an insufficient response to initial therapy.

Methods: We recruited 94 patients with RA and 30 healthy participants. Fecal samples were collected, and the gut microbiome was analyzed by 16S rRNA amplification sequencing. Calypso online software was used to compare microbial composition between groups. For RA patients with moderate-to-high disease activity, treatment was changed after stool collection, and responses were observed 6 months later.

Results: The composition of the gut microbiota in patients with established RA was different from that of healthy participants. Young RA patients (<45 years) had reduced richness, evenness, and distinct gut microbial compositions when compared with older RA patients and healthy individuals. Disease activity and rheumatoid factor levels were not associated with microbiome composition. Overall, biological DMARDs and csDMARDs, except sulfasalazine and TNF inhibitors, respectively, were not associated with the gut microbial composition in patients with established RA. However, the combination of Subdoligranum and Fus��enibacter genera was associated with a future good response to second-line csDMARDs in patients who showed an insufficient response to first-line csDMARDs.

Conclusion: Gut microbial composition in patients with established RA is different from that in healthy individuals. Thus, the gut microbiome has the potential to predict responses of some RA patients to csDMARDs.

ANTI-CITRULLINATED PROTEIN ANTIBODY (ACPA) REACTIVITY TOWARDS NEUTROPHIL-DERIVED ANTIGENS: THE IMPACT OF CLONAL DIVERSITY AND INTER-INDIVIDUAL VARIATION

Background: Why the adaptive immune system turns against citrullinated antigens in rheumatoid arthritis (RA) and whether anti-citrullinated protein antibodies (ACPA) contribute to pathogenesis is questions that have triggered intense research but still are not fully answered. Neutrophils may be crucial in this context, as sources of citrullinated antigens and also as targets of ACPAs.

Objectives: To better understand how ACPAs and neutrophils contribute to RA pathogenesis, we studied the reactivity of a broad spectrum of RA patient-derived ACPA clones to activated or resting neutrophils, and we also compared neutrophil binding using CCP2 captured polyclonal ACPAs from different patients.

Methods: Human neutrophils were isolated from the peripheral blood of healthy volunteers, individuals at risk for RA [1] and patients with established RA. The cells were activated using a Ca2+ ionophore, phorbol 12-myristate 13-acetate (PMA), nigericin, and recombinantly expressed as monoclonal human (h)IgG1 in Expi293F cells, and expressed as polyclonal ACPA in their capacity to affect inflammatory processes in vivo.

Results: ACPAs targeted NET-like structures in all tested conditions but did not bind to the surface of intact cells or influence NETosis. We observed a prominent clonal diversity in the capacity of ACPAs to bind to neutrophil-derived antigens. PAD2 was dispensable but the majority of the clones required PAD4 for neutrophil binding. When using polyclonal ACPA preparations from different patients, we observed high patient-to-patient variability in targeting neutrophil-derived antigens. Similar inter-individual variability was observed in another cellular material. A substantial clonal diversity in targeting neutrophils and a high variability among individuals in both neutrophil binding and osteoclast stimulation suggest that ACPAs may influence RA-related symptoms with high patient-to-patient variability.

Conclusion: Neutrophils can be important sources of citrullinated antigens under conditions that lead to PAD4 activation, NETosis and the extrusion of intracellular material. A substantial clonal diversity in targeting neutrophils and a high variability among individuals in both neutrophil binding and osteoclast stimulation suggest that ACPAs may influence RA-related symptoms with high patient-to-patient variability.

PATIENT-DERIVED ACPA CLONES DISPLAY BOTH PRO- AND ANTI-INFLAMMATORY POTENTIAL IN VIVO

Keywords: Animal models, Rheumatoid arthritis, Autoantibodies

Background: Anti-citrullin protein autoantibodies (ACPA) are known to associate with strong risk factors for rheumatoid arthritis (RA), as well as worse clinical prognosis[1]. Due to their high specificity in RA, ACPA are part of the classification criteria and regarded as being essential in the identification of individuals at risk of developing RA. However, not every ACPA-positive at-risk individual progresses to a clinical diagnosis[2], suggesting that the presence of ACPA per se does not dictate the clinical outcome. We have recently shown that ACPA are in fact predominantly anti-inflammatory and present different biological effects in a murine model of arthritis[3]. Having a wide diversity of ACPA clones isolated from different tissues of RA patients at our disposal, we have continued to analyze different monoclonal as well as polyclonal ACPA in their capacity to affect inflammatory processes in vivo.

Objectives: To determine whether ACPA with pathogenic features, i.e. capable of increasing or sustaining joint inflammation, can be found among different isolated ACPA clones from patients with established RA.

Methods: Immunoglobulin from single B cells from RA patients were sequenced and recombinantly expressed as monoclonal human (h)IgG1 in Exp293F cells, followed by validation of citrulline reactivity. Here, we tested 5 new monoclonal ACPA isolated based on anti-citrullinated tetramer staining of B cells[4]. Polyclonal ACPA from 34 RA patients were enriched as a hACPA-pool. The bound IgG fraction was used as the flow-through control. Arthritis was induced in BALB/c mice by i.v. transfer of 1.5mg of an arthritogenic cocktail of anti-type II collagen (CII) antibodies (Chondrex, USA) followed by administration of 25ug of LPS (E. coli strain O55:B5) 3 days later. Individually, 1mg of purified ACPA monomers, 2mg of ACPA-pool or 2mg flow-through IgG were transferred i.v. together with the arthritogenic antibody cocktail. An isolate control antibody and a non-Arthritis control ACPA clone (hE02 and hNC03, respectively)[3] were used as experimental reference conditions. Arthritis development was monitored daily by a quantitative scoring system of inflamed joints – toes, knuckles, and wrist/ankle of front/hind paws. Statistical analysis was performed with repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Sidak’s multiple comparisons test.

Results: Adding to our previous data with 8 monoclonal ACPA[3], where 3 of them did not alter the disease course, and 4 displayed strong anti-inflammatory properties, we observed an additional 4 newly tested ACPA clones that did not influence arthritis development. Furthermore, we identified one novel monoclonal ACPA (hF2C05) that displays a pro-arthritogenic effect (p<0.01). When assessing a polyclonal ACPA sample, we observed a dominant anti-inflammatory ACPA clone (hE02 and hNC03, respectively)[3] used as experimental reference conditions. Arthritis development was monitored daily by a quantitative scoring system of inflamed joints – toes, knuckles, and wrist/ankle of front/hind paws. Statistical analysis was performed with repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Sidak’s multiple comparisons test.

Background: Since lipid metabolism impact immune cell plasticity regulating cell activation, differentiation and function, the extensive analysis of the lipidomic profile using novel high-throughput metabolomic techniques in chronic inflammatory diseases such as Rheumatoid Arthritis (RA) might contribute to better characterise the pathogenesis of the disease.

Objectives: To analyse the whole lipidomic profile in the serum of RA patients, its association with the disease activity and its modulation by biological and targeted synthetic therapies.

Methods: Two hundred and fifty consecutive RA patients were included in this study. Serum samples and clinical data (disease activity, acute phase reactants, autoimmune profile, etc) were obtained from all subjects. The lipidomic profile was analysed by using nuclear magnetic resonance (NMR) spectroscopy from Nighntigale LTD technology which included more than 200 lipid markers. In parallel, active RA patients from this cohort were prospectively followed up after 6 months of therapy with biologics [anti-TNFα (n=50), anti-IL6R (n=15)], and JAK inhibitors (JAK, n=20) and serum samples were obtained before and after those therapies where changes in the lipid and clinical profile were also evaluated.

Results: RA patients were stratified according to high (68), moderate (117) and low (65) disease activity and approximately 100 lipid markers were significantly altered in the serum of patients from these groups. Interestingly, most of the lipid markers were found reduced in the group of patients with high disease activity including apolipoproteins, cholesterol (free and in lipoproteins), fatty acids (saturated fatty acids (SFA), monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFA)), Omega 3 and 6, Linoleic acid (LA), Docosahexaenoic acid (DHA), triglycerides (alone and in lipoproteins), cholines, phospholipids, lipoproteins [high-density lipoproteins (HDL), low-density lipoproteins (LDL), very low-density lipoproteins (VLDL)], and the total lipid content present in those lipoproteins. These alterations of the lipidomic profile might be associated with an abnormal liver function linked to an exacerbated inflammatory status. Furthermore, multiple correlations were also found among those lipid markers and inflammatory [C-reactive protein (CRP) and erythrocyte sedimentation rate CRP (ESR)] and autoimmune parameters [anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF)]. Interestingly, after six months of therapy, in parallel to the improvement in clinical and analytical profiles of RA patients, a significant upregulation of lipid markers was observed, including common and distinctive molecules reversed by each drug.

Conclusion: The circulating lipidomic profile of active RA patients is deeply reduced and directly linked to the activity of the disease, its inflammatory and autoimmune profile. In parallel to the clinical improvement of the disease, biological therapies and JAK re-establish the altered lipid metabolism.

JANUS KINASE INHIBITOR SUPPRESSES THE DIFFERENTIATION AND FUNCTION OF TUMOR NECROSIS FACTOR-ALPHA AND INTERLEUKIN-6 INDUCED OSTEOLASTS IN PERIPHERAL BLOOD MONOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Disease-modifying drug (DMARDs)

K. Yokota1, Y. Aizaki2, H. Kajiyama3, Y. Araki1, H. Yazawa1, Y. Akiyama1, T. Mimura1. Saitama Medical University, Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama, Japan

Background: We have previously reported that stimulation of mouse bone marrow–derived macrophages with tumor necrosis factor–α (TNF–α) and interleukin-6 (IL–6) induces differentiation of osteoclast-like cells having bone resorption ability[1]. Recently, we have shown that the combination of TNF–α and IL-6 can induce osteoclasts (OCs) from human peripheral blood mononuclear cells (PBMCs) via receptor activator of nuclear factor kappa-B ligand (RANKL)–independent pathways, and that there are functional differences between TNF–α and IL-6 induced OCs and RANKL induced OCs. In particular, the number of TNF–α and IL-6 induced OCs differentiated from PBMCs in patients with rheumatoid arthritis (RA) positively correlated with the modified total Sharp score (mTSS). On the other hands, no such correlation was observed between the number of RANKL induced OCs from RA PBMCs and mTSS[2].

Objectives: We undertook this study to clarify whether Janus kinase (JAK) inhibitors, a new class of disease modifying anti-rheumatic drugs, could inhibit the differentiation and function of TNF–α and IL-6 induced OCs using peripheral blood monocytes (PBMs) derived from patients with RA.

Methods: PBMs derived from RA patients and healthy donors were stimulated by TNF–α and IL-6 or RANKL with or without 10-1000 nm filgotinib, a JAK inhibitor. The number of tartrate-resistant acid phosphatase-positive multinucleated cells induced by TNF–α and IL-6 or RANKL and bone resorption activity using a pit formation assay were assessed. The examination was the number of TNF–α and IL-6 induced or RANKL induced OCs differentiated from PBMs in RA patients before and 6 months after treatment with filgotinib.

Results: The number of TNF–α and IL-6 induced OCs and RANKL induced OCs derived from PBMs in patients with RA was significantly increased compared to that derived from PBMCs in healthy donors (n = 5 each). Addition of filgotinib in vitro significantly inhibited the differentiation of TNF–α and IL-6 induced OCs derived from PBMs of RA patients in a dose-dependent manner. The same concentrations of filgotinib did not inhibit osteoclastogenesis induce by RANKL. Stimulation of RA PBMs by TNF–α and IL-6 in the presence of filgotinib significantly inhibited generation of resorption pits on dentin slices compared to findings in those PBMs in the absence of filgotinib. In contrast, stimulation of RA PBMs by RANKL with filgotinib showed generation of resorption pits in a manner similar to those generated by RANKL without filgotinib. Six months after treatment with filgotinib, the number of TNF–α and IL-6 induced OCs differentiated from PBMs was significantly decreased compared with those before the treatment, whereas no significant change in the number of RANKL induced OCs was observed in the same patients (Figure 1).

Conclusion: Our results suggest that the prevention effect of progressive bone destruction by JAK inhibitor in RA patients may involve inhibition of TNFα and IL-6 induced OC differentiation, as well as suppression of osteoclastic bone resorption activity.

SKELETAL MUSCLE PGCA1A1 PREVENTS ARTHRITIS-INDUCED CAPILLARY RAREFACTION AND IMPEARED GLUCOSE UPTAKE

Keywords: Sarcopenia, Comorbidities, Rheumatoid arthritis

POS1043
Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease with prevalent musculoskeletal complications (Stein et al., 2019, Stein, Santos-Alves, & Lanner, 2020), including metabolic disturbances. Patients with RA have a higher risk of developing type 2 diabetes (T2D) than the general population, however, the causality between RA and T2D is unknown. Skeletal muscle is essential for locomotor activity and the primary site for postprandial glucose disposal.

Objectives: Here we utilized a mouse model of arthritis and mice with chronic elevated expression of the transcriptional co-activator PGC1α1 to elucidate metabolic and functional alterations in skeletal muscle induced by chronic inflammation.

Methods: Arthritis was induced by complete Freund’s adjuvant (CFA, ankle injection) in female wildtype or muscle-specific PGC-1α1 transgenic (MCK-PGC1α1) mice. Glucose uptake (in vivo and ex vivo), immunofluorescence staining, and immunoblotting were assessed 14 days post-CFA injection. Gene expression was analyzed 3 days after CFA induction.

Results: In vivo glucose uptake was reduced by 50-80% in limb muscle (extensor digitorum longus, tibialis anterior, soleus) of mice with arthritis as compared with control mice. Despite this, GLUT4 abundance and membrane translocation were enhanced by ~160% and ~70%, respectively, in limb muscle afflicted by CFA as compared with control. However, no difference was observed in ex vivo glucose uptake between the two groups, suggesting the reduction in glucose uptake was due to an alteration in muscle blood perfusion. Expression of angiogenesis-associated genes, including PGC1α (total and α1 isoforms), VEGF (A and B), and ERR (α and γ) was decreased by 50-70% in muscles afflicted by CFA, which was accompanied by a 25% reduction in muscle capillary density (capillary rarefaction). Muscle specific chronic elevation of PGC1α prevented CFA, which was accompanied by a 25% reduction in muscle capillary density (capillary rarefaction). Muscle specific chronic elevation of PGC1α prevented CFA, which was accompanied by a 25% reduction in muscle capillary density (capillary rarefaction).

Conclusion: Induction of arthritis leads to reduced muscle capillary rarefaction and glucose uptake, which can advance the risk of developing metabolic disease. Strikingly, this pathophysiological development can be corrected by PGC-1α1.

HISTOLOGICAL COMPOSITION OF (TENO)SYNOVIAL AND SYNOVIAL INFLAMMATION IN RHEUMATOID ARTHRITIS ACROSS DISEASE PHASES

Keywords: Synovium, Inflammatory arthritides, Rheumatoid arthritis

L. A. Coletto1, C. Tur1, F. Rubortone1, P. Verardi1, C. Di Mario2, B. Tolusso2, L. Petricca3, M. R. Gigante3, M. Gessi4, M. A. D'agostino5, M. M. Lizzio3, S. Alivernini2,5

Disclosure of Interests: None Declared.

Background: Subclinical tenosynovitis arose as a primary sign of inflammation already in the pre-clinical phases of Rheumatoid Arthritis (RA) and tenosynovitis is a common feature of active state and might persist although sustained remission is achieved. Objectives: To assess the histological features of (teno)synovium from the extensor digitorum tendons of the hand across RA trajectory and to compare it with paired synovial tissue samples.

Methods: Thirty-seven patients underwent minimally invasive ultrasound (US)-guided biopsy of the tenosynovium of extensor digitorum tendons [n=16 with clinically suspected arthralgia (CSA), n=19 with RA (n=4 naive, n=6 resistant to csDMARDs, n=8 to bDMARDs, and n=1 sustained in remission respectively)]. Twenty-three out of 37 patients presenting CSA or clinically evident synovitis in a peripheral joint (whether anatomically adjacent or not to the tendon of interest) underwent US-guided synovial tissue (ST) biopsy also in that location. The Krenn synovitis score (KSS) and the inflammatory infiltrate using CD68/CD21/CD3/CD20 immunohistochemical (IHC) analysis were assessed for each sample.

Results: Tenosynovium belonging to the extensor digitorum compartment of the wrist was successfully collected using a minimally invasive US-guided technique. Representative samples in terms of lining and sublining layers presence in 86.5% and 100% of cases, respectively. Considering the pre-arthritis subgroup, KSS was similar in ACPA/RF pos vs ACPA/RF neg CSA (p=0.5814) and KSS was contingent with RA activity, being significantly higher sublining CD20 pos and CD3 pos cells (for all comparisons p>0.05) between the pre-clinical phase and inflammatory cellular composition in adjacent anatomical sites of the disease state. Semiquantitative analysis showed comparable inflammatory score (KSS) and the inflammatory infiltrate using CD68/CD21/CD3/CD20 immunohistochemical (IHC) analysis were assessed for each sample.

Conclusion: (Teno)synovium is a retrievable tissue through a minimally invasive procedure across RA trajectory and its inflammation is directly related to the disease state. Semiquantitative analysis showed comparable inflammatory degree and inflammatory cellular composition in adjacent anatomical sites of the same person.

IN ANTI-CCP POSITIVE AT RISK INDIVIDUALS, WHICH BIOMARKERS CHANGE PRIOR TO PROGRESSION TO INFLAMMATORY ARTHRITIS?

Keywords: Descriptive studies, Autoantibodies, Rheumatoid arthritis

L. Duquenne1, K. Harnden1, L. Garcia-Montoya1, A. Di Matteo1, R. Chowdhury1, J. Nam1, N. Sidhu1, K. Mankia1, P. Emery2

Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: The pre-clinical phase of inflammatory arthritis (IA) can be prolonged. Although many baseline biomarkers have shown predictive value for progression to IA, their evolution during the disease continuum remains unclear.

Objectives: To investigate which biomarkers change before progression to IA and assess their predictive value in the next 6 months.

Methods: In a single centre prospective cohort, 472 at-risk individuals were recruited with a positive anti-cyclic citrullinated peptide antibody (anti-CCP Ab) and a new musculoskeletal symptom, but without clinical arthritis. They were followed prospectively until IA occurred. Sequential data on early morning stiffness (EMS) duration, erythrocyte sedimentation rate (ESR), anti-CCP2 Ab value, rheumatoid factor (RF) value, number of small joints tender on examination, number of joints with power Doppler grade ≥1 (PD≥1), health assessment questionnaire (HAQ), visual analog scale for general health (VAS GH), global pain (VAS GP), and fatigue (VAS fatigue) were analysed. Three time-intervals were investigated within the progression (P) group: less than 6 months (P<6M), 6 to 12 months (P 6-12M), and over 12 months before progression to IA (P>12M).

Paired analysis (Wilcoxon signed rank and McNemar tests) were used to compare P<6M and P>12M (PU), P<6M and P6-12M (PB) within the P group. Independent analyses (Mann Whitney U and Fisher’s tests) were used to compare the pre-progression (NP) and P groups. Time-intervals for NP visits were adjusted to P visits by time elapsed since first visit. Multivariate predictive analysis of change in biomarkers was done using random effects panel data using robust standard errors, adjusted for age and gender. Significant difference was defined by p<0.05.

Results: Paired analysis within P group showed significant increase in PU for RF, EMS, ESR, number of small joints tender, HAQ, and VAS GP, and in PB for EMS and VAS GP (Figure 1). After dichotomisation, significant increases were also found for EMS ≥30min, ≥1 joint PD≥1, VAS GP ≥50mm, ESR positive, and ≥1 small joint tender. Analysis between P and NP groups showed significant differences in anti-CCP2 Ab, RF, ESR, number of joints PD≥1, number of small joints tender on examination, and HAQ at multiple time-intervals (Figure 1). EMS and VAS GP were only different at P<6M. Multivariate panel data analysis showed predictive value in the change of anti-CCP2 Ab ≥3x upper limit of normal (ULN) (OR 51, p=0.041), positive RF (OR 7, p=0.002), ESR ≥30min (OR 9 p=0.004), and abnormal ESR (OR 7, p=0.046) for progression to IA within 6 months.

Conclusion: In anti-CCP2 Ab at-risk individuals, a change in predictive biomarkers occurs in the 6 months prior to IA development. Whilst EMS and VAS GP only show a late increase, multivariate panel data analysis suggest that anti-CCP2Ab ≥3xULN, positive RF, EMS ≥30min and positive ESR predict IA development within the next 6 months. These observations may be of value for monitoring at-risk individuals.

Keywords: Genetics/epigenetics, Inflammatory arthritides, Rheumatoid arthritis

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease characterized by systemic and localized bone impairment. Bone erosions, the hallmark lesions of RA, are an important predictor of disability, disease severity, and mortality. The arising of bone erosions is triggered by chronic inflammation, mediated mainly by immune cells. Under inflammatory conditions, classical (CD14++CD16-) monocytes are the main source of osteoclasts precursors, the accountable cells responsible for bone resorption process. Although previous transcriptomic studies have shown that CD14++CD16- monocytes have high expression of genes involved in inflammation and in extracellular matrix degradation process, there is no data regarding the impact of CD14++CD16- monocytes on bone destruction in RA.

Objectives: To analyze CD14++CD16- monocytes transcriptomic profile from RA patients presenting bone erosions evaluated by high-resolution peripheral quantitative computed tomography (HR-pQCT), comparing with RA patients without bone erosions and healthy controls.

Methods: Thirty-nine premenopausal RA women were included in this study. Based on bone erosion identification on metacarpophalangeal and proximal interphalangeal joints of the dominant hand assessed by HR-pQCT, RA patients were classified into two groups according to the presence or absence of bone erosions. Twenty age- and body mass index-matched healthy subjects were enrolled in the control group. CD14++CD16- monocytes were indirectly isolated using the CD16 MicroBeads, and RNA-Sequencing was performed. Transcriptome analysis of CD14++CD16- monocytes from control group were used to account for background expression. The differentially expressed genes (DEGs) were identified and the analysis of the biological pathways was performed using bioinformatics tools.

Results: RNA-seq analysis revealed 1140 DEGs in RA patients with erosion, of which 89 were up-regulated and 1051 down-regulated compared to the group of patients without erosion. A top ranked genes suggested that the up-regulated genes were highly associated with immune response and cytokine activation. Interestingly, the down-regulated genes were associated with bone formation and wound healing (Table 1). Enriched pathways in patients with erosion were associated with substantial activation of immunity and inflammation. Pathways associated with osteoblast differentiation and the regulation of Wnt signaling were less activated in RA patients with erosion. Interestingly, while the activity of immune pathways was positively correlated with the number of bone erosions, a negative correlation was observed between the number of erosions with osteoblast differentiation and regulation of cell matrix adhesion.

SEMAPHORIN3B PROMOTES A RESOLVING-INFLAMMATION PHENOTYPE IN MACROPHAGES FROM RHEUMATOID ARTHRITIS PATIENTS

Keywords: Genetics/epigenetics, Rheumatoid arthritis, Cytokines and chemokines

S. Martínez-Ramos1, C. Rafael Vidal1, B. Malvar Fernández1, N. Perez-Gomez1, C. Mouríño Rodríguez1, F. J. Maceiras-Par1, I. Altubás González2, J. M. Pego-Reigosa1, S. García1, Galicia Sur Health Research Institute (IIS Galicia Sur), SERGAS-UVIGO, Rheumatology & Immuno-Mediated Diseases Research Group (IRIDIS), Vigo, Spain

Background: Our group have recently shown that (Sema)phorin3B is reduced in RA patients and plays a protective role in an arthritis mouse model, through the reduction of inflammatory mediators and the synovial fibroblast invasiveness and was associated with a reduction of CD68 positive synovial macrophages (Igea, 2022). On the other hand, MerTK is a receptor protein kinase involved in the resolution of inflammation and plays a protective role in arthritis mice models (Waterborg, 2018). A recent study has shown that a population of synovial tissue macrophages characterized by the expression of MerTK are associated with remission maintenance and with an anti-inflammatory phenotype of RA FLS (Alivernini, 2020).

Objectives: The aim of this study is to determine the role of Sem3B in the phenotypic characteristics of RA macrophages and the implication of MerTK.

Methods: Peripheral blood monocytes from RA patients (n=10) were differentiated into macrophages by culturing in the presence of IFN-γ (10 ng/mL) for 6 days. Afterwards, macrophages were stimulated for 24 h with LPS (10 ng/mL). Sem3B (200 ng/mL) or the combination of both mediators. The expression of pro- and anti-inflammatory mediators was determined by quantitative PCR (qPCR) and ELISA. The expression of MerTK and macrophage surface markers was measured by flow cytometry.

Results: Sem3B did not modulate the macrophage expression of pro-inflammatory mediators IL1B, IL6, IL12B, IL23, TNF, CCL2, CXCL10 and CD86, but significantly reduced the LPS-induced expression of these mediators (Figure 1A), as well as the protein secretion of IL6, IL12p70 and TNF. In addition, Sem3B alone, but not in combination with LPS, significantly induced the gene and protein expression of MerTK and the secretion of Resolvin D1, a MerTK-mediated lipid involved in resolution of inflammation (Figure 1B). Moreover, Sem3B reduced the expression of the M1 marker CD64, while induced the expression of the M2 marker CD163.

Conclusion: Our data demonstrate that Sem3B modulates the macrophage phenotype of RA macrophages, inducing a skewing towards an anti-inflammatory/pro-resolving phenotype, likely in a MerTK-dependent manner. Therefore, here we identified a new mechanism involved in the protective role of Sem3B in RA pathogenesis.

INTERLEUKIN 40 IS INCREASED IN THE SERUM OF INDIVIDUALS AT RISK OF RHEUMATOID ARTHRITIS AND STIMULATES AN INFLAMMATORY RESPONSE IN MONONUCLEAR CELLS VIA NFκB

Keywords: Cytokines and chemokines, Biomarkers, Rheumatoid arthritis

A. Navrátilová1,2, K. Pražijerová1, N. Petrovská1,2, P. Pavelka1,2, J. Vencovsky1,2, L. Šenolt1,2, M. Filková1,2, L. Andres Cerezo1,2. Institute of Rheumatology, Prague, Czech Republic, Department of Rheumatology, Prague, Czech Republic; 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Department of Rheumatology, Prague, Czech Republic

Background: Interleukin 40 (IL-40) is a new cytokine implicated in the pathogenesis of several autoimmune disorders including rheumatoid arthritis (RA). Recently, we found an association of IL-40 with the early stages of RA and demonstrated the pro-inflammatory potential of IL-40 on neutrophils.

Objectives: As the period preceding clinically apparent RA has not yet been fully described with respect to clinical biomarkers, we aimed to investigate IL-40 in individuals who are at risk of RA and to assess its functional mechanism in immune regulation in peripheral blood mononuclear cells (PBMCs).

Methods: IL-40 was determined in the serum of individuals at risk of RA (defined as patients with arthralgia with no clinical arthritis at baseline who are either carriers of anti-citrullinated protein antibodies, ACPA, or meeting the EULAR definition of clinically suspect arthralgia) at baseline (n=179) and at the time of arthritis manifestation in patients who progressed to clinical arthritis (n=25). IL-40 was also analysed in the serum of age and sex-matched healthy controls (n=60). In vitro experiments were performed on PBMCs from at-risk individuals (n=10). PBMCs were exposed to recombinant IL-40 (10, 50, 100, and 250 ng/ml) and LPS. For inhibition studies, cells were pretreated with NFκB inhibitor prior to incubation with IL-40. Levels of IL-40 and IL-6 were measured by commercially available ELISA kits.

Results: Serum IL-40 was significantly up-regulated in at-risk individuals compared to healthy individuals (4.8 ± 0.2 vs. 1.5 ± 0.09 ng/ml, p<0.0001). Moreover, the levels of IL-40 were significantly higher in the serum of double-positive (ACPA+/rheumatoid factor, RF+) compared to double-negative at-risk individuals (n=10). PBMCs were exposed to recombinant IL-40 (10, 50, 100, and 250 ng/ml) and LPS. For inhibition studies, cells were pretreated with NFκB inhibitor prior to incubation with IL-40. Levels of IL-40 and IL-6 were measured by commercially available ELISA kits.

Conclusion: This is the first study to demonstrate the up-regulation of IL-40 in the serum of individuals at risk of RA. Moreover, we showed that IL-40 induces the pro-inflammatory response in PBMCs at-risk individuals via NFκB dependent pathway.

Rheumatoid arthritis - comorbidity and clinical aspects

**Keywords:** Rheumatoid arthritis, Lungs, Disease-modifying drug (DMARDs)

**POS1050 INCIDENCE RATES OF INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT: A POST HOC POOLED ANALYSIS FROM A COMPREHENSIVE OF CLINICAL TRIALS**

**Background:** Interstitial lung disease (ILD) is a recognized complication of RA. Prior studies have suggested stabilization or improvement of ILD in patients with RA (RA-ILD) treated with abatacept.[1,2] Few studies have evaluated the background study rate of ILD.

**Objectives:** To determine the incidence rate of clinically significant ILD in a cohort of patients with RA receiving abatacept + MTX versus placebo + MTX from multiple clinical trials.

**Methods:** This retrospective analysis examined pooled safety data from ten phase 3 clinical trials of patients with RA treated with background MTX in combination with abatacept or placebo. The term ‘interstitial lung was used to identify incidences of ILD reported as AEs in the safety data. The exposure period for each patient was censored at first incidence of clinically significant ILD, 56 days after last study drug administration, or 1 day prior to commencement of another study drug, whichever occurred first. Poisson regression models were used to estimate crude incidence rates per 100 person-years for baseline risk factors within treatment groups, and to estimate incidence rate ratios for the placebo + MTX versus abatacept + MTX treatment groups. Disease activity parameters, DAS28 (CRP) and HAQ-DI, were estimated from baseline to the time of ILD diagnosis (as reported by AEs).

**Results:** In total, 3,708 patients (10,521 person-years) treated with abatacept + MTX and 999 patients (938 person-years) treated with placebo + MTX were included. Patients treated with placebo + MTX had a higher incidence rate of ILD per 100 person-years (95% CI) versus those treated with abatacept + MTX (0.43 [0.16–1.14] vs 0.10 [0.05–0.18], respectively; Figure 1). The incidence rate ratio of placebo + MTX versus abatacept + MTX treatment groups for the total population was 4.49 (95% CI: 1.23–13.42). For all subpopulations stratified by baseline risk factors (where > 1 patient in each treatment group had an ILD event), incidence rate ratios were > 2. Patients with RA aged ≥ 55 years, BMI < 30 kg/m², no history of smoking, no baseline DMARD use other than MTX, no prior TNF inhibitor use, corticosteroid use, high DAS28 (CRP) status, and RF or anti-citrullinated protein antibody (ACPA) positivity were all significantly less likely to develop ILD if treated with abatacept + MTX versus placebo + MTX (Figure 1).

**Conclusion:** Incidence rates of ILD among patients with RA were significantly lower in those treated with abatacept + MTX than placebo + MTX, both in the total analysis population and subpopulations stratified by baseline risk factors. This suggests a possible protective benefit of abatacept on the incidence rate of RA-ILD. Limitations of this post hoc analysis include the different observation period lengths of the 2 treatment arms due to the optimization of clinical trials and the low number of patients with ILD events overall. However, the low incidence rate of ILD observed here is consistent with previously reported studies.[3]

**Background:** Lung involvement is a prevalent extrarticular manifestation of rheumatoid arthritis (RA) that remains a significant clinical challenge. Few studies have comprehensively quantified lung abnormalities of RA patients using artificial intelligence-based (AI) technology.

**Objectives:** The aim of this study was to quantify lung lesions in RA patients and classify them based on their lung parameters.

**Methods:** An AI-based quantitative computed tomography (CT) image analysis software (AIQCT) was applied to high-resolution CT scans of RA patients in a cross-sectional manner. AIQCT automatically classified and quantified 10 types of parenchymal image patterns, expressing the volumes as percentages of total lung volume (V). Hierarchical Ward's linkage clustering based on these patterns identified five clusters. Visual assessments (ILD, and airway lesions) of HRCT and clinical phenotypes were assessed.

**Results:** A total of 408 RA patients were included in the study. The lung profiles of the five clusters were as follows: Cluster I (68.6%), characterized by nearly normal lungs; Cluster II (23.5%), characterized by slight lung lesions with honeycombs or ground-glass opacities (GGOs); Cluster III (5.6%), characterized by the
preponderance of GGos; Cluster IV (1.0%), characterized by a predominant hyperlucent area; and Cluster V (1.2%), characterized by extensive lung abnormalities (Figure 1, Table 1). The number of patients in each cluster with ILD and airway lesions, based on visual assessments, were as follows: [ILD] Cluster I, 1/280 (0.3%); Cluster II, 1/96 (1.0%); Cluster III, 5/23 (21.7%); Cluster IV, 0/4 (0%); and Cluster V, 5/5 (100%) (p < 0.001); [airway lesions] Cluster I, 31/280 (11.1%); Cluster II, 29/96 (30.2%); Cluster III, 6/23 (26.1%); Cluster IV, 0/4 (0%); and Cluster V, 1/5 (20%) (p < 0.001). Clinical characteristics of each cluster were described in Table 1. The disease activity of RA in each cluster were as follows: [DAS28ESR, mean (SD)] Cluster I, 2.4 (1.0); Cluster II, 3.0 (1.2); Cluster III, 2.8 (1.0); Cluster IV, 2.2 (0.7); and Cluster V, 3.0 (0.8) (p < 0.001); [HAQ, mean (SD)] Cluster I, 0.4 (0.6); Cluster II, 0.9 (0.9); Cluster III, 1.1 (0.9); Cluster IV, 0.3 (0.3); and Cluster V, 0.8 (0.9) (p < 0.001).

Conclusion: This study is the first to classify lung lesions in comprehensive RA patients using quantitative data derived from novel AI technology. The AIQCT-derived clustering of RA patients appears to be associated with their clinical backgrounds and characteristics.

**Prevalence of Fibrosing Progressive Interstitial Lung Disease in Rheumatoid Arthritis Patients**

**Keywords:** Lungs, Rheumatoid arthritis

**Background:** Intestinal lung disease (ILD) related to rheumatoid arthritis (RA) significantly impacts on quality of life and survival of the patients. Data about prevalence and natural history of RA-ILD are only partially known and mainly based on retrospective studies. The recent introduction of antifibrotic drugs has allowed for the first time the opportunity to treat ILD in RA patients; in fact, INBUILD study demonstrated the efficacy of nintedanib in the treatment of progressive fibrosing ILD different than idiopathic pulmonary fibrosis (IPF), including RA-ILD, but the prevalence of RA-ILD patients that may potentially benefit from nintedanib therapy remain unknown.

**Aims:** Aim of the present multicenter Italian study was to investigate the prevalence of fibrosing progressive patterns in a cross-sectional cohort of non-selected RA-ILD patients.

**Methods:** We enrolled in the study all RA patients according to 2010 EULAR/ACR classification criteria, with an ILD confirmed at high resolution computed tomography (HRCT) and with a follow-up of at least 24 months. According to the current indication of nintedanib, patients were defined as having a progressive fibrosing ILD in case of a relative decline in forced vital capacity (FVC) ≥10% predicted and/or an increased extent of fibrotic changes on chest imaging in a 24-month-period. Respiratory symptoms were excluded to reduce possible bias due to the retrospective interpretation of cough and dyspnea.

**Results:** One hundred and thirty-four RA-ILD patients were enrolled in the study (males/females 54/80, mean age 72±9.5 years, mean RA and ILD duration 13.1±9.5 and 4.6±4.1 years, respectively). Anticitrullinated peptides antibodies (ACPA) and rheumatoid factor (RF) were recorded in 76.2% and 87.6% of cases, respectively. According to radiologic features, ILD was classified as probable or definite usual interstitial pneumonia (UIP) in 50.7% of patients, NSIP in 19.4% and other patterns in 29.8%. A fibrotic pattern was reported in 73.9% of cases (all patients with UIP pattern, 57.7% of patients with NSIP and 40% with other pattern). A relative decline of 6.8% of forced vital capacity (FVC) was recorded during the follow-up, without significant difference between fibrosing and non-fibrosing ILD (6.3%±13.8 vs 5.9±12.3%, respectively). A relative FVC decline ≥ 10% and/or a progression of radiologic fibrotic involvement was observed in 38.8% of patients. As expected, a significant difference in relative decline of FVC was recorded between progressive and non-progressive ILD (15.7%±16.4 vs -1.3%±8.3, respectively).

**Conclusion:** The recent introduction of nintedanib for the treatment of fibrosing progressive ILD different by IPF has potentially changed the paradigm for the treatment of RA-ILD. In fact, for the first time, rheumatologist has a therapy available with efficacy on RA related lung involvement. This study shows some limitations. The retrospective design and the need of serial HRCT and FVC could underestimate the prevalence of progressive lung disease. Finally, some patients were already treated with antifibrotic drugs, possibly influencing the evolution of lung disease in the last 2 years. In conclusion, about a third of RA-ILD patients shows a fibrosing progressive pattern of ILD and might benefit of antifibrotic treatment, alone or in combination with anti-rheumatic drugs. For RA patients with progressive non-fibrosing ILD, we need more studies to establish the best therapeutic approach.

Background: Interstitial lung disease (ILD) can have a significant impact on the long-term outcome in patients with rheumatoid arthritis (RA) but international screening guidelines for early diagnosis of RA-ILD are lacking. It is unknown to date how RA patients are screened for ILD in clinical practice. An analysis of patients’ experiences and perspectives will help identify current practice and guide future directions to optimize screening, management and patients care.

Objectives: To identify patients’ experiences and unmet clinical needs regarding screening for RA-ILD.

Methods: An international multidisciplinary panel of 18 ILD experts developed and distributed an online-based survey in 12 languages for RA patients with and without ILD from August to December 2022 to receive self-reported data. User representatives of relevant patient associations and RA patients with and without ILD refined and piloted the survey questions. The survey covered management strategies, including information about awareness of ILD, screening for ILD and patient perspectives on future directions. The study was approved by the Ethics committee of the University Clinic Heidelberg, Germany, and patients consented before starting the online survey.

Results: In total, 1132 RA patients from 11 countries answered the survey. Mean age was 57 (SD13.6) years, 129 (12%) were males, 690 (75%) had seropositive RA activity, mean (SD) 4.4 (2.4) for ILD, of which 75% by x-ray, 49% by high-resolution computed tomography (HRCT), 49% with pulmonary function test (PFT), 23% with respiratory symptoms, 40% with auscultation and 194/387 (59%) were screened with several modalities. Older age, male sex, presence of other lung comorbidities and treatment with Rituximab or Abatacept were associated with screening assessed by PFT (OR 3.42, 95%CI 2.11-5.36, p<0.001) and Smoker, n (%) 499 (47) 182 (49) 261 (45) Any comorbidity, n (%) 630 (58) 252 (66) 322 (54) RA activity, mean (SD) 4.4 (2.4) 4.4 (2.4) 4.5 (2.5) Male, n (%) 129 (12) 72 (19) 41 (7) Female, n (%) 603 (55) 297 (77) 375 (73) Seropos RA, n (%) 57 (13.6) 59 (13.2) 55 (13.8) Smoker, n (%) 499 (47) 182 (49) 261 (45) Any comorbidity, n (%) 630 (58) 252 (66) 322 (54) MTX, n (%) 693 (61) 244 (63) 380 (62) bDMARD, n (%) 566 (52) 226 (58) 298 (49) RA activity, mean (SD) 4.4 (2.4) 4.4 (2.4) 4.5 (2.5) Male, n (%) 129 (12) 72 (19) 41 (7) Female, n (%) 603 (55) 297 (77) 375 (73) Seropos RA, n (%) 57 (13.6) 59 (13.2) 55 (13.8) Smoker, n (%) 499 (47) 182 (49) 261 (45) Any comorbidity, n (%) 630 (58) 252 (66) 322 (54) MTX, n (%) 693 (61) 244 (63) 380 (62) bDMARD, n (%) 566 (52) 226 (58) 298 (49)

Conclusion: Based on this self-reported patient survey, information about ILD provided to RA patients is frequently limited. Only one third are screened for ILD. The majority of patients stated a clear need for more information on RA-ILD, increasing awareness of lung involvement in RA should be a priority in clinical practice and research.

Table 1. Disease characteristics of all RA patients, and patients screened and not screened for ILD

![Figure 1](image-url)
Background: Quantitative computed tomography (QCT) methods have been developed to automatically quantify parenchymal lung features on chest CT imaging. There have been limited investigations of QCT in RA participants and non-RA comparators or studies of the mortality impact of QCT features in RA.

Objectives: Determine the association and mortality impact of QCT features in RA and non-RA participants.

Methods: We analyzed associations between RA and QCT features in COPDGene, a multicenter cohort study of current or former smokers that excluded participants with known interstitial lung disease or bronchiectasis. We identified participants with and without RA using RA self-report and DMARD use. We assessed the lung parenchyma in each scan by categorizing regions of interest into normal lung, interstitial changes, or emphysema using the local tissue density and distance from the pleural surface. Interstitial changes were subclassified into nodular, subpleural, and reticular, and classified as subpleural line, ground glass, and honeycomb.

Results: We identified 82 RA cases and 8820 non-RA comparators. RA was associated with a lower percentage of normal lung (85.8% vs. 91.0%, p=0.0001), increased interstitial changes (70% vs. 4.8%, p=0.0001), and no statistical difference in emphysema (2.6% vs. 1.9%, p=0.09) compared to non-RA comparators.

In linear regression analyses adjusted for age, sex, smoking status, pack-years, BMI, and other lifestyle factors, the combination of RA and >75th percentile of emphysema had significantly higher mortality (HR 5.56, 95%CI 2.71-11.38) with <75th percentile of emphysema.

Conclusion: Using machine learning-derived QCT data in a cohort of smokers, we found that RA was associated with increased interstitial changes, even after adjustment for smoking and other lifestyle factors. The combination of RA and emphysema conferred greater than 5-fold increased mortality.

POS1056 CYTOKINE ANALYSIS IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Cytokines and chemokines, Biomarkers

J. M. Lisboa1,2,3, A. Muñeces1,2, B. Oliver-Martos1,2,4, G. Díaz-Cordobes1,2, I. Ureta1, R. Redondo1, S. Manrique Arija1,2,3, A. Fernandez-Nebro1,2, M. N. Mené-Vázquez1,2,3, Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Biodián, Enfermedades Inmunitarias y Autoinmunes, Málaga, Spain; 1Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain; 2Universidad de Málaga, Departamento de Medicina y Dermatología, Málaga, Spain; 3Hospital Regional Universitario de Málaga, UGC de Neurociencia, Málaga, Spain

Background: Intestinal lung disease (ILD) is the most frequent non-pleural
manifestation in rheumatoid arthritis (RA) and causes high morbidity and mortality [1-3]. Currently, there are no clinically useful serum markers for the diagnosis and prognosis of RA associated ILD (RA-ILD) [4].

Objectives: To identify soluble cytokines that work as biomarkers for diagnosis and prognosis in RA-ILD and explore whether there is an association between those and pulmonary progression.

Methods: Observational case-control study nested in a prospective cohort of cases of patients with RA (ACR/EULAR 2010) [5] with and without ILD, paired by sex, age, and time of RA evolution. All subjects underwent pulmonary function tests (PFTs) and high-resolution computed tomography (HRCT) on the inclusion date (protocol date) and, in cases of RA-ILD, also on diagnosis of ILD. The primary variable ILD was defined according to lung biopsy or HRCT according to the American Thoracic Society/European Respiratory Criteria [6], and pulmonary progression was defined as worsening FVC >10% or DLCO >15% [4]. Inflammation variables included inflammatory activity data measured by DAS28-ESR and a cytokine multiplex including Th1/Th2 function, inflammatory cytokines, and chemokines. Other clinical, RA severity and therapeutic variables were also studied: rheumatoid factors (RF), anti-cyclic citrullinated peptide antibodies (ACPA), radiological erosions, and Health Assessment Questionnaire (HAQ) values. A descriptive analysis and two Cox regression models were performed to identify factors associated with ILD and ILD progression in RA, adjusting for time to development of ILD-RA and to ILD progression, respectively.

Results: A total of 70 subjects were included, 35 RA-ILD cases and 35 RA controls without ILD (Table 1). A higher percentage of patients with RA-ILD compared to the rest, presented elevated RF (p=0.089) and ACPA levels (p=0.031), higher DAS28-ESR values (p=0.032), number of swollen joints (p=0.040) and worse quality of life measured by HAQ (p=0.003). The variables that were independently associated with ILD and a cytokine multiplex including Th1/Th2 function, inflammatory cytokines, and chemokines. Other clinical, RA severity and therapeutic variables were also studied: rheumatoid factors (RF), anti-cyclic citrullinated peptide antibodies (ACPA), radiological erosions, and Health Assessment Questionnaire (HAQ) values. A descriptive analysis and two Cox regression models were performed to identify factors associated with ILD and ILD progression in RA, adjusting for time to development of ILD-RA and to ILD progression, respectively.

Conclusion: Patients with RA-ILD show higher inflammatory activity than RA patients without ILD. Some cytokines are associated both with diagnosis and with a worse prognosis in patients with RA-ILD, so they could be potential bio-
markers for this entity. Future studies are needed to validate these data and confirm the findings.

POS1057 LUNG ULTRASONOGRAPHY AS A SCREENING TOOL FOR INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Ultrasound, Rheumatoid arthritis, Systematic review

A. Alunno1, S. Bellando Randone2, E. Pintus3, N. Piccini4, J. Schoones5, M. Matsuuchi-Cerinc4,5, Internal Medicine and Nephrology Unit, University of L’quila, Department of Life, Health and Environmental Sciences, L’quila, Italy; 2Division of Rheumatology, AOU, Dept. Experimental and Clinical Medicine, University of Firenze, Florence, Italy; 3Leiden University Medical Center, Directorate of Research Policy (formerly Walaeus Library), Leiden, Netherlands; 4IRCCS San Raffaele Hospital, UniRRA, Milan, Italy

Background: In rheumatoid arthritis (RA), interstitial lung disease (ILD) is a frequent pulmonary manifestation which is responsible for a high morbidity and mortality. Chest high resolution computed tomography (HRCT) is the imaging gold standard for the diagnosis and characterisation of ILD. Recently, the use of lung ultrasonography (US) has been suggested as a valid, less invasive and radiation-free tool in the pulmonary screening process.

Objectives: To review the reliability of lung US as a screening tool for the diag-

nosis of ILD in RA patients.

Methods: A systematic literature search in several databases was con-
ducted following the PICO framework on July 2022. Two researchers inde-
pendently screened abstracts and titles, and full texts were subsequently
reviewed to determine eligibility (original research articles enrolling adult RA
patients undergoing lung US and HRCT). Data from eligible articles were
extracted and risk of bias was assessed with validated tools. Owing to ex-
tensive interstudy heterogeneity, narrative summaries had to be used to
to present the data.

Results: Out of 890 retrieved papers, only 7 were eligible and only 5 of them
enrolled a control group (Table 1). All studies had a cross-sectional design and no
follow-up data were available. Although all studies relied on the US identification
of B-lines, the number of intercostal spaces assessed as well as the threshold/
threshold score to classify the findings as ILD or no-ILD varied across studies. Fur-

more, some studies also focused on the irregularities of the pleural line. The
sensitivity of lung US ranged between 62.2 and 97.1% while specificity ranged
between 89 and 100%. However, the studies’ heterogeneity did not allow any
comparison. In RA patients with neither respiratory symptoms nor previous ILD
diagnosis, the concordance in identifying pathological findings between US and
HRCT ranged between 90 and 100%.

Figure 1. Cox regression analysis adjusted for time of evolution of RA

Conclusion: Patients with RA-ILD show higher inflammatory activity than RA patients without ILD. Some cytokines are associated both with diagnosis and with a worse prognosis in patients with RA-ILD, so they could be potential bio-
markers for this entity. Future studies are needed to validate these data and confirm the findings.

Conclusion: Our Systematic Literature Review shows that lung US may have a role as screening tool for ILD in RA and also in asymptomatic patients. The implementation of the routine use of lung US in RA might allow an early identification and a prompt treatment of RA-ILD patients as well. However, the harmonization of US findings is required to allow either for the comparison of research studies and for a broad implementation of lung US in clinical practice.

POS658 CORRELATION BETWEEN SERUM KL-6 AND ANTI-MODIFIED PROTEIN ANTIBODIES (AMPAS) IN RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Biomarkers, Lungs, Rheumatoid arthritis

J. C. Sarmiento-Monroy1, A. Pérez-Isidro2,3, R. Castellanos Moreira4,5, V. Ruiz6, B. Frade-Sosa1, A. Azuaga1, J. Ramírez7, M. J. Gomora7, C. García-Moreno7, I. Haro8, A. Colmenero8, M. Morales-Ruiz9,10, E. Ruiz-Ortiz9,10, V. Viñas9,10,11, F. Hernández-González11, J. Sellares8,9, J. D. D. Cañete11, R. Sanmartí11, J. A. Gómez-Puerta11, H. Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Immunology, Barcelona, Spain; 4. Hospital Clinic of Barcelona (Grant # 37 933) and the Spanish Ministry of Economy and Competitiveness (Grant # RTI2018-094120-B-I00).

Background: Some studies have shown that Krebs von den Lungen-6 (KL-6) may be a valuable biomarker for diagnosis and stratifying prognosis in Rheumatoid Arthritis-Associated Interstitial Lung Disease (RA-ILD). Cytokinna and carboxylation are responsible for generating Anti-Modified Protein/Peptide Antibodies (AMPAs) and are associated with RA-ILD.

Objectives: To evaluate the correlation between serum KL-6 and AMPAs in patients with RA.

Methods: We conducted a cross-sectional study that included patients with RA (ACR/EULAR 2010 criteria) with available KL-6 and AMPAs data measured in blood serum at study enrolment. ILD was diagnosed by high-resolution computed tomography and confirmed by a multidisciplinary committee. Serum KL-6 levels were measured by Lumipulse G KL-6 Kit (FujiRebio, Japan), using Chemiluminescent enzyme immunoassay (CLEIA). The reference value for KL-6 in healthy subjects was 118-627 U/mL. The inter-assay variation coefficient of the reagent was ≤ 4.4%. AMPAs repertoire tested included ACPA, anti-carbamylated protein antibodies (anti-CarP), and autoantibodies to malondialdehyde-acetaldehyde (anti-MAA). ACPA, anti-CarP, and anti-MAA were determined by made-by-hand ELISA tests. Antigens, cut-off values, and isotypes tested are depicted in Table 1. Spearman’s rank correlation coefficient was used to analyze the correlation between serological markers.

Results: A total of 128 patients were included (24 RA-ILD and 104 RA-non-ILD). Patient characteristics were as follows: female 73%, mean age 60.3 ± 12.4 years, mean disease duration 6.5 ± 4.7 years, RF positive 66%, anti-CCP positive 83.6%, erosive disease 54.7%, and mean DAS28 2.94. Most patients received treatment with methotrexate 84 (65.6%), glucocorticoids 72 (56.3%), and biological DMARDs 23 (18.0%). Among RA-ILD patients, the median FVC and DLco (% predicted value) were 79 (IQR 74.7–88.7) and 62.9 (IQR 53.1–70.6), respectively. Usual interstitial pneumonia (UIP) was found in 11/24 (45.8%) patients. The mean KL-6 level was 478.4 ± 400.9 U/mL. KL-6 levels were elevated in 22 patients (172%). Serum levels of KL-6 in the RA-ILD group were significantly higher than those in the RA-non-ILD group (756.0 ± 673.4 U/mL vs. 411.9 ± 273.0 U/mL; p=0.001). Serum KL-6 had a moderate positive correlation with HSA-MAA IgA (r=0.56; p=0.048) in patients with non-UIP pattern (Figure 1). Anti-CarP (Fib IgG: 81.8% vs. 54.7; p=0.019) and anti-MAA antibodies (HSA-MAA IgA: 36.4% vs. 10.4; p=0.018) were significantly associated with elevated KL-6 values (Table 1).

Conclusion: Serum KL-6 is a surrogate biomarker of ILD, elevated in a subgroup of patients with RA. ILD-KL-6 elevation correlated with some AMPAs, such as anti-CarP and anti-MAA. Whether AMPAs are potential biomarkers for RA-ILD requires further analysis.

Funding: Hospital Clinic of Barcelona (Grant # 37 933) and the Spanish Ministry of Economy and Competitiveness (Grant # RTI2018-094120-B-I00).

ASSOCIATION OF THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE WITH ARTERIAL INFLAMMATION, ASSESSABLE WITH 18F-FUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY, IN RHEUMATOID ARTHRITIS

**Keywords:** Cardiovascular disease, Biomarkers

Columbia University, Department of Medicine, New York;
United States of America;
Brigham & Women’s Hospital, Department of Medicine, Boston, United States of America;
Mount Sinai Medical Center, Translational and Molecular Imaging Institute, New York, United States of America;
Massachusetts General Hospital, Department of Medicine, Boston, United States of America

**Background:** Rheumatoid arthritis (RA) and atherosclerosis share many common inflammatory pathways. Reducing the activity of inflammatory pathways with immunomodulators may lessen the risk of cardiovascular disease in RA. As such, a multi-biomarker of RA disease activity (MBDA; AKA the Vectra Score) could serve as an indicator of treatment-associated improvements in atherosclerotic plaque inflammation.

**Objectives:** To prospectively evaluate the association of an MBDA score and its components with the change in arterial inflammation in RA patients enrolled in a clinical trial of two different RA treatment strategies.

**Methods:** In the TARGET Trial, patients with active RA despite methotrexate were randomly assigned to the addition of either a TNF inhibitor (TNNI) or sub-fasalasane-hydroxychloroquine (triple therapy). Baseline and 24-week follow-up 18F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) scans were assessed for change in arterial inflammation measured as the maximal arterial target-to-background ratio (TBR) of FDG uptake in the most diseased segment (MDS) of either the carotid arteries or aorta (TBRmax MDS). The MBDA score, measured at baseline and weeks 6, 18, and 24, was assessed for its association with the change in arterial inflammation. The MBDA score was categorized as low, moderate, and high disease activity (LDA, MDA, and HDA; LDA<30, MDA 30-44, HDA>44 units).

**Results:** Among the 150 randomized TARGET participants, 112 had an interpretable TBR at baseline and trial conclusion (24 weeks) (mean age 60 years; 71% female; RA duration 1.4 years; baseline DAS28-CRP=4.8). The MBDA score at week 24 was significantly correlated with the change in TBRmax MDS (Spearman’s rho=0.239; p=0.011), while the baseline and interim MBDA scores were less strongly and not significantly correlated with the change in TBRmax MDS. The week 24 MBDA score remained significantly associated after adjustment for relevant confounders. Neither the baseline, follow-up, or change in DAS28-CRP nor CRP significantly predicted the change in TBRmax MDS. There was no significant difference in the association of the MBDA score with the change in arterial inflammation between the two randomized treatment groups. Those achieving MBDA LDA at week 24 had a statistically significant adjusted reduction in TBRmax MDS of 0.35 TBR units, while no significant reductions in TBRmax MDS over time were observed in those remaining in MBDA MDA or HDA (Figure 1A). The component of the MBDA score with the strongest association with change in TBRmax MDS was serum amyloid A (SAA) (Spearman’s rho=0.239; p=0.011), while the baseline and interim MBDA scores were less strongly and not significantly correlated with the change in TBRmax MDS. The week 24 MBDA score remained significantly associated after adjustment for relevant confounders. Neither the baseline, follow-up, or change in DAS28-CRP nor CRP significantly predicted the change in TBRmax MDS. There was no significant difference in the association of the MBDA score with the change in arterial inflammation between the two randomized treatment groups. Those achieving MBDA LDA at week 24 had a statistically significant adjusted reduction in TBRmax MDS of 0.35 TBR units, while no significant reductions in TBRmax MDS over time were observed in those remaining in MBDA MDA or HDA (Figure 1A). The component of the MBDA score with the strongest association with change in TBRmax MDS was serum amyloid A (SAA) (Spearman’s rho=0.239; p=0.011), while the baseline and interim MBDA scores were less strongly and not significantly correlated with the change in TBRmax MDS.

**Conclusion:** Achieving low disease activity by the MBDA at 24 weeks was associated with a clinically meaningful reduction in arterial inflammation, similar to high-intensity statins, in a way not predicted using other RA disease activity measures, suggesting that treatment-associated improvements in arterial inflammation may be indicated by specific biomarkers that overlap those used to track arthritic disease activity.

**Acknowledgements:** We would like to acknowledge the investigators of the TARGET Trial Consortium and the patients that participated in the trial. The trial was funded by NIH-NIAAA U01-AR068043; Abbvie and Amgen supplied study drug. Crescendo Biosciences funded and performed the assays for the MBDA testing.

HUMORAL RESPONSES AGAINST HDL ARE LINKED TO LIPOPROTEIN TRAITS, ATHEROSCLEROSIS, INFLAMMATION AND PROTEOMIC PATHOGENIC PATHWAYS DURING EARLY ARTHRITIS STAGES

**Keywords:** -omics, Cardiovascular disease, Autoantibodies

Università degli Studi di Messina, Rheumatology, Messina, Italy

**Background:** Cardiovascular (CV) risk excess in rheumatoid arthritis (RA) cannot be solely attributed to traditional CV risk factors. Chronic inflammation and immune dysregulation are crucial mechanisms for atherosclerosis development in RA. Recent evidence suggests a link via humoral responses against high-density lipoproteins (HDL) and its components. However, their exact specificity, clinical relevance and emergence along disease course are unknown, especially during the earliest phases of arthritis.

**Objectives:** To characterize the specificity and clinical relevance as predictors of anti-HDL responses along during the earliest phases of arthritis.

**Methods:** IgG and IgM serum levels of antibodies against HDL (anti-HDL) and Apolipoprotein A1 (anti-ApoA1) were measured in 82 early RA patients (EULAR/ACR classification criteria), 14 arthralgia individuals (EULAR definition) and 96 controls. Established RA patients (n=42) were included for validation. Atherosclerosis occurrence and vascular stiffness were measured by Doppler-ultrasound. Lipoprotein content, particle numbers and size were measured by NMR. Cytokines were measured by immunosays. A cardiometabolic-related protein panel was evaluated using high-throughput targeted proteomics.

**Results:** IgG and IgM anti-HDL and anti-ApoA1 responses were increased in early RA compared to controls (both p<0.001) and were comparable to established disease. Only IgG anti-ApoA1 antibodies were associated with higher lipoprotein traits (HDL and ApoA1) and Apolipoprotein A1 (anti-ApoA1) were measured in 82 early RA patients (EULAR/ACR classification criteria), 14 arthralgia individuals (EULAR definition) and 96 controls. Established RA patients (n=42) were included for validation. Atherosclerosis occurrence and vascular stiffness were measured by Doppler-ultrasound. Lipoprotein content, particle numbers and size were measured by NMR. Cytokines were measured by immunosays. A cardiometabolic-related protein panel was evaluated using high-throughput targeted proteomics.

**Conclusions:** Low disease activity by the MBDA at 24 weeks was associated with a clinically meaningful reduction in arterial inflammation, similar to high-intensity statins, in a way not predicted using other RA disease activity measures, suggesting that treatment-associated improvements in arterial inflammation may be indicated by specific biomarkers that overlap those used to track arthritic disease activity.

A 4-year randomized controlled trial of the two different RA treatment strategies.
Conclusion: Humoral responses against HDL particles are an early event along arthritis course, although quantitative and qualitative differences can be noticed among stages. These differences informed distinct capacities as biomarkers (incremental value) and underlying pathogenic circuits. Anti-HDL but not anti-ApoA1 were robust predictors of lipoprotein features, inflammatory milieu and subclinical CV burden in early RA.

DOI: 10.1136/annrheumdis-2023-eular.136
Background: The observation in the ORAL SURVEILLANCE trial[1] of an increased rate of major cardiovascular (CV) events (MACE) in patients with rheumatoid arthritis (RA) treated with Janus kinase inhibitors (JAKis) recently prompted the EMA’s Pharmacovigilance Risk Assessment Committee (PRAC) to suggest significant restrictions for MACE in comparison with the PRAC recommendation in a real-life cohort of RA patients treated with JAKis.

Objectives: Assessing the performance of a CV risk chart developed and validated for RA (Expanded Risk Score in RA [ERS-RA][2,3]) in quantifying the risk for MACE in comparison with the PRAC recommendation in a real-life cohort of RA patients treated with JAKis.

Methods: A retrospective analysis on all RA patients treated with a JAKi in a tertiary care academic hospital was conducted. According to PRAC recommendation, the study population was stratified into patients at increased (>65 years old; current or former long-term smokers; patients carrying increased risk of MACE, defined according to ORAL SURVEILLANCE trial[1] inclusion criteria (>90 years old and having at least one CV risk factor)) or not CV risk. The same stratification was also calculated with the ERS-RA[2,3], using a 10% increase in 10-year risk of MACE as a cut-off for the definition of increased CV risk. The incidence of MACE was calculated over a mean follow-up period of 3 years and was correlated with the two different definitions of CV risk considered.

Results: The study population included 194 RA patients exposed to JAKis for a total of 337 patient-years. The baseline characteristics of enrolled population has been fully described in Table 1. According to PRAC definition, CV risk was considered increased in 80 (41.2%) patients (n=27 [33.8%] >65 years old; n=25 [31.2%] smokers). Calculated with the ERS-RA, the CV risk was found to be increased in 36 (18.6%) patients. Over the follow-up period, we observed only one MACE (a non-fatal stroke) in a patient who met the definition of increased CV risk according to both criteria. The specificity of ERS-RA score was 0.82 (positive predictive value 0.03), whereas the specificity of PRAC criteria was 0.59 (positive predictive value 0.01).

Conclusion: Our study shows that in a real-life setting the use of a validated score chart as ERS-RA allows CV risk to be calculated more accurately in RA patients undergoing JAKis than the strict application of the PRAC recommendation. Further prospective observational studies on larger populations are advocated to better define CV risk assessment in this scenario.

Background: Uncontrolled inflammation increases the risk for cardiovascular (CV) and venous thromboembolic (TE) events. Reducing inflammation using advanced therapies (AT) is expected to reduce these risks. Clinical registries are best for precise observations on diagnosis, reasons for drug withdrawal, and disease activity. Administrative databases are more comprehensive for comorbidities and outcomes.

Objectives: To compare the incidence of CV and TE events before and after AT initiation in the same rheumatoid arthritis (RA) patients, to explore specific toxicities or poorer protection of some ATs.

Methods: USRAT Registry combines administrative and clinical data. Our team is the single one treating rheumatology patients among over 500,000 people. All their inpatient episodes are recorded in the administrative system of one single multisite hospital. Since 2003, we developed a registry of 1800+ patients treated with AT. Episodes of inpatient care for these patients were extracted from our hospital’s database from 1995 up to the end of 2021. Clinical charts were revised to confirm diagnosis and disease activity over time. We report severe CV and TE events occurring over the 3 years before and the 3 years after initiation of a first AT in patients for which chart revision is currently completed. We analyzed data according to initial AT, identifying a large subset remaining on first AT (First Persistent), a small subset who stopped first AT but did not switch (First-Stop), and others who switched AT over the period (Switch).

Results: RA was confirmed in 596 (66.3% women; mean age 59.1). Mean disease duration at first AT initiation (anti-TNF in 61%) was 7.3 years. First Stop patients trended to be men (47.6%) vs 34.8% (First Persistent) and 30.1% (Switch) (p = 0.074). Switch patients were younger (57.9 yo vs 59.8 First Persistent and 60.8 First Stop) (p = 0.04). Mean duration of first AT treatment was similar in Switch and First-Stop (0.94 vs 0.93 y), versus 5.3 in First Persistent.

Département de Statistiques, Montpellier, France

Background: Pre-diabetes was associated with an increased risk of all-cause
mortality and cardiovascular disease (CVD) in the general population. However, data exploring the effect of pre-diabetes on the risk of CVD in patients
with inflammatory arthritis (IA), including rheumatoid arthritis (RA) and psoriatic
arthritis (PsA), were limited.
Objectives: To evaluate the effect of pre-diabetes on the risk of major cardiovascular events (MACE) in patients with IA.
Methods: A population-based cohort of IA patients was identified in the citywide platform (The Hospital Authority Data Collaboration Lab) of the Hong Kong
Hospital Authority. IA patients recruited from 2006 to 2015 were followed until
the end of 2018. Time-varying Cox proportional hazard models with time-varying
fasting glucose (FG) levels were analyzed to identify the risk of having MACE in
IA patients.
Results: A total of 13,905 (12,233 RA and 1,672 PsA) patients with IA were
recruited. After a total of 119,571 patient-years of follow-up, 934 (7.0 %) patients
developed a first MACE. At baseline, the mean age of the entire cohort was
56.9±14.4 (RA: 57.7±14.4 vs. PsA: 51.0±12.8, p<0.001), mean disease duration
was 0.6±1.5 (RA: 0.7±1.5 vs. PsA: 0.3±1.0, p<0.001) and the proportion of patients
with diabetes was 3.6% (RA: 3.4 vs. PsA: 5.4, p<0.001). Using multivariable Cox
regression analysis, in IA patients who were not on any anti-diabetic medications, the time-varying FG level of a prediabetic state (5.6-6.9 mmol/L) was found
to be independently associated with a higher risk of MACE (HR 2.54, 95%CI
1.50-7.71, p<0.001 in the ESR model; HR 2.43, 95%CI 1.97-2.99, p<0.001 in the
CRP model) (Table 1), after adjusting for age, sex, and baseline cardiovascular

Background: Patients with rheumatoid arthritis (RA) experience premature
mortality that is largely due to cardiovascular disease (CVD). Ample evidence
suggests that elevated γGT activity is associated with increased risk of CVD.
We have previously showed that replacing ESR by γGT in DAS28 calculation
(DAS28-γGT) allowed a combined evaluation of cardiovascular risk in patients
with RA, in addition to joint disease activity [1].
Objectives: To validate the predictive value of the DAS28-γGT for the occurrence of major cardiovascular events (MACE) in the ESPOIR cohort.
Methods: We conducted a prospective observational study including patients
with RA from the ESPOIR cohort fulfilling the 2010 ACR/EULAR criteria. Patients
were recruited between 2002 and 2005 and were followed up to 10 years.
Patients with a history of cardiovascular disease and not followed up to 1 year
were excluded from the analysis. DAS28-γGT was calculated at baseline using
the following formula: 0.56*√TJ-28 + 0.28*√SJ-28 + 2*ln (γGT)+0.014*GH. Our
primary outcome was the occurrence of MACE during the observation period.
Results: 720 RA patients (77% females) were considered with a mean age of
48±13 years and a mean disease duration of 93±185 days. Disease activity was
high, with a mean DAS28 of 5.1±1.3. At baseline, the DAS28-γGT correlated
with age (r=0.26, p<0.001) and the Framingham risk score (r=0.31, p<0.001).
The DAS28-γGT was also significantly increased in males (10.3±1.8 vs. 9.4±1.9,
p<0.001) and in patients presenting the following conditions: high alcohol consumption (11.2±1.8 vs. 9.5±1.9, p<0.001), active smoking (9.72±1.93 vs. 9.44±1.86,
p=0.036), blood hypertension (10.2±2.01 vs. 9.44±1.85, p<0.001), diabetes mellitus (10.67±2.20 vs. 9.53±1.87, p=0.001), hypercholesterolemia (9.95±1.97 vs.

Keywords: Inflammatory arthritides, Cardiovascular disease, Comorbidities


9.50a±1.88, p=0.017) and obesity (BMI > 30 kg/m²) (10.01±1.90 vs. 9.26±1.83, p<0.001). No association was observed between DAS28-GT and treatment with NSAIDs or corticosteroids. The DAS28-GT steadily increased according to cardiovascular risk (Figure 1A) and was significantly increased in patients with at least 2 cardiovascular risk factors (Figure 1B). A total of 35 MACE was recorded during the observation period, with a mean time to event of 70±44 months. ROC curve analysis indicated that DAS28-GT >9.4 had the best sensitivity (74%) and specificity (62%) for the diagnosis of MACE during the observation period. Increased DAS28-GT (>9.4) was predictive of the occurrence of MACE, with a hazard ratio (HR) of 3.05 (95% confidence interval, CI 1.44-6.43) (Figure 1C). Multivariate Cox analyses confirmed increased DAS28-GT together with age and diabetes mellitus as independent predictors of MACE (Table 1). The DAS28 was not predictive of the occurrence of MACE in this cohort.

Conclusion: The DAS28-GT was identified in this large prospective cohort as an independent predictor of MACE in patients with RA. In addition to the assessment of disease activity, the DAS28-GT is a simple and useful tool to evaluate CV risk in routine and warn the clinician about the CV risk burden in patients with RA.

WHERE HAVE ALL THE RHEUMATOID NODULES GONE?

Keywords: Rheumatoid arthritis, Epidemiology, Skin

B. Kimbrough1, H. Langenfeld2, C. S. Crowson1, J. M. Davis III1, E. Matteson1, E. Myasoedova1, Mayo Clinic, Rheumatology, Rochester, United States of America; Mayo Clinic, Quantitative Health Sciences Division of Clinical Trials and Biostatistics, Rochester, United States of America

Background: The most common extraarticular manifestation of rheumatoid arthritis (RA) is the rheumatoid nodule, which is reported to affect about 30% of patients with RA.[1] The development of rheumatoid nodules has been associated most strongly with high disease activity, seropositive status, and more rapid progression of joint destruction. Despite significant changes in RA treatment and decreasing incidence of seropositive RA, no recent population-based studies have assessed the epidemiology of rheumatoid nodules.

Objectives: We aim to investigate changes in rheumatoid nodule incidence over time.

Methods: This study evaluated rheumatoid nodule incidence trends using an inception cohort that included all adult patients from a geographically well-defined area who met the 1987 American College of Rheumatology criteria for RA between 1/1/1985 and 12/31/2014. Patients were followed until the earlier of death, migration from the region, or 12/31/2000 (for patients with incident RA in 1985-1994) or 12/31/2008 (for 1995-2007 patients) or 10/15/2022 (for 2008-2014 patients). Patients were divided into two cohorts based on the incidence date of RA, an early cohort from 1985-1999 and a later cohort from 2000-2014. Medical records were reviewed manually, and the incidence date of rheumatoid nodules was recorded if determined to be present either by clinical judgment and/or histopathology. The 10-year cumulative incidence of rheumatoid nodules was estimated in each cohort. Cox proportional hazard models adjusted for age, sex and calendar year were used to determine associations between specific demographic and RA disease data with rheumatoid nodules.

Results: 907 patients were included in this study, 296 (67% female) in the 1985-1999 cohort and 611 (70% female) in the 2000-2014 cohort. The mean follow-up period between these cohorts, respectively, was 9.1 and 7.4 years. Baseline characteristics (earlier cohort, latter cohort) included rheumatoid factor (RF) positive (70%, 59%), joint erosions in the first year of RA (24%, 29%), and ever smoker (57%, 47%). The 10-year cumulative incidence of rheumatoid nodules was 31% in the 1985-1999 cohort and 16% in the 2000-2014 cohort (hazard ratio [HR] 0.52, 95% confidence interval [CI] 0.39-0.70). Identified risk factors for the development of rheumatoid nodules included RF positivity (HR 4.38, 95%CI 2.37-8.09), erosions (HR 2.53, 95%CI 1.64-3.91), current smoker (HR 2.09, 95%CI 1.30-3.37), male sex (HR 1.77, 95%CI 1.14-2.73), methotrexate use (HR 1.77, 95%CI 1.09-2.86) and other DMARDs (HR 2.07, 95%CI 1.14-3.74) (Table 1).

Conclusion: The incidence of rheumatoid nodules has decreased substantially over time. More research is needed to understand the drivers of this improvement and implications on RA disease outcomes.

MORBIDITIES ASSOCIATED WITH SERIOUS INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Epidemiology

B. Kimbrough1, C. S. Crowson1, R. Lennon2, J. M. Davis III1, A. Strangfeld3, E. Myasoedova1, Mayo Clinic, Rheumatology, Rochester, United States of America; Mayo Clinic, Quantitative Health Sciences Division of Clinical Trials and Biostatistics, Rochester, United States of America; German Rheumatism Research Centre (DRFZ) Berlin and Charite University Medicine, Epidemiology, and Health Services Research, Berlin, Germany

Background: Patients with rheumatoid arthritis (RA) are at increased risk for serious infections (SI) and have a higher prevalence of multimorbidity. The increased risk for SI has led to the creation of multiple infection risk models over the last decade for patients with RA. These models often include combinations of patient demographics, medications, and a limited list of morbidities. However, the limited number of morbidities included in these models are not fully reflective of the morbidity burden seen in real-world practice. Thus, some morbidities that contribute to SI risk may be absent from the existing models.
Objectives: We aim to examine associations between a comprehensive list of morbidities and SI in patients with RA.

Methods: This population-based cohort study evaluated morbidities as risk factors for SI by including all adult patients from a geographically well-defined area from 1/1/1999 through 12/31/2013 who met the 1987 American College of Rheumatology criteria for RA. Patients were followed until the earlier of: death, migration from the region, or morbidities and SI in patients with RA.

Objectives: Scientific Abstracts

[2] Crowson CS, Hoganson DD, Fitz-Gibbon PD, Matteson EL. Development of SI prevention strategies and treatment approaches in patients with RA. Morbidity burden is an important clinical characteristic that may influence patients with RA, and this risk is not completely accounted for in two SI risk score adjusted models, 12 and 23 morbidities were associated with increased risk, adjusted only for age, sex, and calendar year. In the RABBIT and Mayo SI risk score adjusted models, 12 and 23 morbidities were associated with increased risk, respectively. Morbidities conferring high risk among the three adjusted models are included. Figure 1. Specific morbidities included in the RABBIT and Mayo SI risk scores continued to have large and significant effect sizes despite adjustment (Figure 1). The number of morbidities was also associated with SI risk, leading to a 16% (initial), 11% (RABBIT), and 13% (Mayo) increase in SI risk per morbidity.

Conclusion: Several morbidities are associated with increased risk of SI in patients with RA, and this risk is not completely accounted for in two SI risk scores. Morbidity burden is an important clinical characteristic that may influence SI prevention strategies and treatment approaches in patients with RA.

SYSTEMATIC LITERATURE REVIEW INFORMING THE EULAR POINTS TO CONSIDER TASK FORCE ON THE INITIATION OF TARGETED THERAPIES IN PATIENTS WITH INFLAMMATORY ARTHRITIDES AND A HISTORY OF CANCER

**Keywords:** Comorbidities, bDMARD, Malignancy

**Disclosure of Interests:** Jacques Morel Speakers bureau: Amgen, Biogen, Bristol Myers Squibb, Fresenius Kabi, Janssen, Lilly, Merck Sharp and Dohme, Medac, Mylan, Nordic Pharma, Novartis, Pfizer, Roche Sanofi, Sandoz, Union Chimique Belge, Consultant of: Abbvie, Boehringer Ingelheim, Galapagos, Glaxo Smith Kline, Pfizer, Grant/research support from: Pfizer, Novartis, Bristol Myers Squibb, Lilly, Olivier Brocq; None declared, Cécile Gajoulu-Viala: None declared, Arnaud Constant: None declared, Slim Lassoud: None declared, Emmanuelle Dernis: None declared, Christophe Richez: None declared, Cédric Lukas: None declared, Claire Daire: None declared, Claire Duflos: None declared.

DOI: 10.1136/annrheumdis-2023-eular.4126

**Background:** Potential associations between targeted therapies in patients with an inflammatory arthritis (IA) and malignancy are a frequent concern in daily rheumatology practice. No specific framework has been proposed to evaluate the benefit-risk balance of initiating or reinitiating a targeted therapy (bDMARDs/csDMARDs) in patients with a history of cancer.

**Objectives:** To perform a systematic literature review (SLR) to inform the task force formulating the EULAR Points to Consider on the initiation of targeted therapies in patients with IA and a history of cancer.

**Methods:** Specific research points were defined with the task force before formulating the research questions with a librarian under supervision of two methodologists. The task force agreed to focus the SLR on clinical data in patients treated with any targeted therapy for an inflammatory or autoimmune rheumatic or skin or bowel disease. All studies up to the 15th July 2022 were searched through PubMed and Embase. Inclusion criteria required studies reporting on the initiation of a targeted therapy in patients with history of cancer, a control group, and a history of cancer.

**Results:** A total of 1555 publications were identified of which 79 articles fulfilled inclusion criteria, including 13 published articles and 1 EULAR abstract. All studies were high quality observational data from cohorts or registries, representing 4522 patients (13030 patient-years). Most of the patients included were treated for rheumatoid arthritis. The previous cancer was a solid cancer for more than 90% of the patients. The targeted therapy evaluated was a TNF inhibitor in all the studies, and 4 studies evaluated rituximab as well. The overall HR of cancer recurrence was 1.02 (0.83-1.26) in patients treated with a targeted therapy compared to those treated with a conventional DMARD (Figure 1). In patients treated with a TNF-inhibitor, the HR was 1.01 (0.86-1.18). In subgroup analyses, no difference in cancer recurrence was observed if the targeted therapy was initiated before or after 5 years since the diagnosis of the initial cancer; no difference in cancer recurrence was observed depending on the initial cancer type.

**Conclusion:** The SLR informing EULAR PTC show that overall, the targeted therapies and clinical context covered by the included studies were not associated with an increased risk of cancer recurrence when compared with conventional synthetic DMARDs. This SLR also shows the lack of data for other targeted therapies, for other clinical contexts, and for other conditions than RA.

* adjusted for age, sex, number of used DDMARDs in the 2 years prior to the index date, concurrent use of cDMARDs and corticosteroids, comorbidities (diabetes mellitus and chronic obstructive respiratory diseases), dosage (as percentage of defined daily dose) and follow-up time adjusted for age, sex, dosage (as percentage of defined daily dose) and follow-up time.

Table 1. Number of infections and IRR for 1) bDMARD and JAKi users, 2) baricitinib and tofacitinib

Main analysis: bDMARD vs JAKi

RESULTS: In total, 14,898 patients were included, with 20,050 treatment episodes with either JAKi or bDMARDs. Most patients were female (72%) and median age was 61 years (IQR 52-70). Infection IRs were higher in JAKi (48/100 patient years) compared to bDMARDs (35/100 patient years), adjusted incidence rate ratio (IRR) 1.22, 95% CI 1.12-1.33) (Table 1). No significant differences in infection IRs were found between JAKi baricitinib and tofacitinib. In older patients, absolute infection IRs were higher (overall infection IR 42/100 patient years for age ≥ 65 vs 31/100 patient years for age < 65). However, comparing JAKi to bDMARDs, IRs were similar for all ages (adjusted IRR for age ≥ 65 1.31 (95% CI 1.15-1.49), adjusted IRR for age < 65 1.17 (95% CI 1.05-1.30)).

CONCLUSION: JAKi are - compared to bDMARDs - associated with a slightly higher infection risk and a higher risk of HZ specifically. In older patients, absolute infection IRs are higher but relative infection risks for JAKi versus bDMARDs are similar in all age groups. No differences in infection risk between tofacitinib and baricitinib were found.

Disclosure of Interests: None Declared.
Background: Patients with Rheumatoid Arthritis (RA) have a higher prevalence of comorbidities, compared to the general population. The presence of such comorbidities has been directly associated with an increased disease activity. However, little is known about the impact of comorbidities in the therapeutic response and in the retention rate.

Objectives: a) To evaluate the effect of comorbidities on the first biologic disease-modifying anti- rheumatic drug (bDMARD) effectiveness in patients with RA after 2 years of follow-up, and b) to determine the influence of such comorbidities on the first bDMARD retention rate.

Methods: The study population consisted of patients with a diagnosis of RA and exposed to a first bDMARDs, included in BIOBADASER. BIOBADASER is a prospective, large national drug safety registry of patients with rheumatic diseases exposed to b- or tsDMARDs. Patients were classified in two groups at baseline according to the Charlson Comorbidity index (CCI) score: <3 and ≥3. Patients achieving remission (DAS28<2.6) at 1 and 2-years timepoints after the anti-TNF initiation were compared between the two groups using chi-square test. The absolute DAS28 score over time was compared between both groups of patients using a linear regression model adjusted for sex and age, and considering the follow-up visit as covariate. Finally, the first bDMARD retention rate was compared between the two groups using Log-Rank test and Kaplan-Meier curve.

Results: A total of 1253 patients initiating bDMARD were included (76.6% female and mean age 56 years at the beginning of therapy). Overall, 107 (9%) patients had a CCI ≥3, being diabetes the most frequent comorbidity (5.0%). No differences were found in DAS28≥3 between patients with CCI<3 and CCI≥3 after 1 year of follow-up (48.2% vs. 44.2%, p-value=0.457), nor after 2 years (50.8% vs. 40.7%, p-value=0.135). The linear regression model showed significant higher scores in DAS28 over the two years in patients with a CCI ≥3 after adjusting for age and sex (beta coefficient 0.27, 95%CI: 0.02-0.51; p-value=0.034). Finally, no differences in the bDMARD retention rate were found between both groups (median 2.6 years [IQR: 1.5-4.1] in CCI<3 vs. 2.1 years [IQR: 0.6-3.7] in CCI≥3; log rank test p-value 0.467) (Figure 1).

Conclusion: These data suggest that a higher CCI in patients with RA is associated with greater DAS28 scores during the first two years after bDMARD initiation, although no differences in remission status were found. In addition, a slightly shorter retention rate was found in patients with CCI≥3, although the difference was non-significant. These results suggest a lower probability of disease activity control in patients with comorbidities after the initiation of bDMARD.

POS1074 COMORBIDITIES AND EXTRA-ARTICULAR INVOLVEMENT IN PERSISTENT INFLAMMATORY AND NON-INFLAMMATORY DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS AND CONTROLS

Keywords: Rheumatoid arthritis, Cardiovascular disease, Comorbidities
Conclusion: Fibromyalgia was associated with D2TRA-NIRRA. Otherwise, we did not find a strong association between comorbidities or extra-articular manifestations and D2TRA. There were trends for more serious infections, gastrointestinal diseases and extra-articular manifestations in D2TRA-PIRR. Our results suggest that the current definition of D2TRA may not adequately identify D2TRA patients with a substantial burden of comorbidities.

Reumatologia, Martina Franca, Italy

Background: An increased number of elderly patients with rheumatoid arthritis (RA) has been observed in the last years mainly due to the increase in life expectancy. In this group it is possible to include two different categories: patients with onset of RA in advanced age (60-65 years old), and patients with an early occurrence of RA aged with the disease. For all elderly patients many factors such as: comorbidities and polytherapy, extra-articular manifestations of RA, and the process of immune-senescence can increase frailty and difficulties for rheumatologist in management of RA. Although patients with late onset of RA frequently show more aggressive articular involvement and systemic manifestations, literature data suggest that rheumatologists tend to treat elderly patients less aggressively. Moreover, they delay treat to target approach with less frequent use of biologic drugs and prolonged use of steroids or NSAIDs.The improvement of knowledge about persistence of different drugs and associated patients’ profiles could suggest more specific treatment strategies encouraging the correct management of RA elderly patients in clinical practice.

Aim of the study was to evaluate the retention rate at two years of treatment with biologic or targetted synthetic (ts) DMARDs, namely TNF inhibitors, anti-IL-6, anti-CD20, Abatacept and Janus kinases inhibitors (JAKis), in patients with RA who received a targeted therapy over 65 years of age.

Methods: Data were extracted from the GISEA registry (Gruppo Italiano Studio Early Arthritis), selecting RA patients in which biologic- or ts-DMARDs were prescribed over 65 years of age.

Results: We analysed data of 1221 patients (F/M ratio 968/253). Therapies prescribed were: TNFis in 362 pts (29.6%), anti-IL-6 in 199 pts (16.3%), JAKis in 304 pts (24.9%), anti-CD20 in 53 pts (4.3%), abatacept in 303 pts (24.8%). Median time of persistence in therapy was 181 weeks (confidence interval 95% 158-205), with a significant difference among different classes of drugs (abatacept 254 weeks, CIA95% 219-289; anti-CD20 221, 104-337; TNFis 164, 151-217; JAKis 139, 115-164; and anti-IL-6 136, 105-167, p<0.001). Retention rate at two years was 66.3%±3.8 for abatacept, 59.7%±8.8 for anti-CD20, 54.9%±3.7 for TNFis, 49.2%±0.5 for anti-IL-6, 52.7%±3.7 for JAKis (Figure 1). A multivariate analysis including age, gender, class of drug, line of treatment, disease activity index on 28 joints (DAS28) was performed. Anti-cilutinulated peptides antibodies, rheumatoid factor, combination therapy with glucocorticoids and methotrexate were excluded from the model, since not significant at univariate analysis. Multivariate analysis revealed that treatment with TNFis (HR 1.63 CI 1.01-2.63, p=0.044), treatment with anti-IL-6 (HR 1.43 CI 1.11-1.85, p=0.006), an increase of 1 point of DAS28 (HR 1.21 CI 1.08-1.35, p=0.001) correlated with lower retention rate at two years. Among 1220 pts considered, 33.5% discontinued therapy. The most frequent cause of discontinuation for all drugs was a secondary loss of efficacy in 49.3% of cases.

Conclusion: In our study abatacept resulted the drug with the highest retention rate among drugs prescribed in elderly patients. On the other side, anti-IL6 showed the lowest persistence. Disease activity and the therapeutic choice may influence the retention rate. Our results on a very large population represent interesting points to consider for the choice of treatment for elderly RA patients. Prospective studies should be advisable to confirm these data.

POS1076 ARE DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS FOR RHEUMATOID ARTHRITIS ASSOCIATED WITH A LOWER RISK OF DEMENTIA? A SYSTEMATIC REVIEW WITH META-ANALYSIS

Keywords: Comorbidities, Rheumatoid arthritis, bDMARD

W. Xie1, Z. Zhang1. 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Dysregulation of several inflammatory cytokines including tumor necrosis factor (TNF) in dementia patients has also been identified as a key factor in the pathogenesis of rheumatoid arthritis (RA). Existing epidemiologic evidence suggests an increased risk of incident dementia associated with RA. Modulating systemic inflammation with disease-modifying anti-rheumatic drugs (DMARDs) is hypothesized to attenuate the development of dementia.

Objectives: We aimed to investigate the association of DMARDs therapy for RA with risk of incident dementia.

Methods: Electronic database searches of PubMed, EMBASE and Cochrane Library were performed. Observational studies that assessed the association of dementia with DMARDs in RA were included. Pooled risk ratios (RRs) with 95%
The median age was 54.9 (interquartile range: 44.0–64.5). 5,142 (88.2%) were seropositive, and the proportion of seropositive status differed between 2000–2010 (n=4,261) and 2011–2021 (n=2,004) (Figure 1). The proportion of seropositive patients was 90.2% in 2000–2010 and 84.0% in 2011–2021. The positivity for RF and anti-CCP antibody was decreased over time: 74.9% and 78.1% in 2000–2010 and 70.0% and 74.3% in 2011–2021, respectively. The time period (2011–2021) was associated with seronegativity (adjusted odds ratio [OR]: 1.51, 95% confidence interval [CI]: 1.24–1.83). Additionally, the time period (2011–2021) was also associated with RF negativity (adjusted OR: 1.44, 95% CI: 1.23–1.68) and anti-CCP negativity (adjusted OR: 1.30, 95% CI: 1.10–1.52).

Acknowledgements: The IORRA cohort data revealed a decrease in seropositivity in Japanese patients with RA. The phenotype of RA in the clinical setting may have been changing over time.

REFERENCES:

Keywords: Rheumatoid arthritis, Real-world evidence

Methods: This is a retrospective study using data from the Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort. Among patients enrolled in the IORRA cohort between 2000 and 2021, patients with a disease duration of <3 years at enrolment were excluded. Seropositive status was defined as positive for rheumatoid factor (RF) (cut-off: 15 IU/mL) and/or anti-cyclic citrullinated peptide (CCP) antibody (second generation; cut-off: 4.5 IU/mL). Patients with one negative and one unmeasured or both unmeasured were excluded. The time period was divided into 2000–2010 and 2011–2021. The effect of the time period on seropositivity was analyzed using multivariable analysis after adjusting for age, sex, smoking, and body mass index (BMI) at enrolment.

Results: Of 6,514 patients enrolled, 5,289 (81.2%) patients were female, and the median age was 54.9 (interquartile range: 44.0–64.5). 5,142 (88.2%) were seropositive, and the proportion of seropositive status differed between 2000–2010 (n=4,261) and 2011–2021 (n=2,004) (Figure 1). The proportion of seropositive patients was 90.2% in 2000–2010 and 84.0% in 2011–2021. The positivity for RF and anti-CCP antibody was decreased over time: 74.9% and 78.1% in 2000–2010 and 70.0% and 74.3% in 2011–2021, respectively. The time period (2011–2021) was associated with seronegativity (adjusted odds ratio [OR]: 1.51, 95% confidence interval [CI]: 1.24–1.83). Conclusion: The IORRA cohort data revealed a decrease in seropositivity in Japanese patients with RA. The phenotype of RA in the clinical setting may have been changing over time.
Background: High-dose glucocorticoids (GCs) can cause weight gain and hypertension. It is unclear whether GCs at ≤7.5mg/d prednisone equivalent (“low dose”), administered for rheumatoid arthritis (RA), do as well. Prior studies could not definitively answer this research question: Observational studies are confounded by indication, and individual randomized trials (RCTs) are usually underpowered for small safety signals.

Objectives: To assess the effects of long-term treatment with low dose GCs in RA on body weight and blood pressure by pooling individual patient data from RCTs.

Methods: Data from five RCTs with two-year interventions were pooled. All trials originated in Europe and allowed concomitant treatment with DMARDs. Intervention groups received GCs at a dose of ≤7.5mg/d prednisone equivalent, control groups received placebo or nothing. Co-primary outcomes were the difference in change from baseline in a) body weight (kg) and b) mean arterial blood pressure (MAP; mmHg). A secondary outcome was the difference in the number of administered antihypertensive drugs. Several sensitivity and subgroup analyses were conducted. All analyses were based on analyses of covariate-adjusted mean change from baseline. All primary and secondary analyses were performed with a hierarchical statistical testing procedure was followed. Results: 1,112 participants were included (mean ± SD age 61 ± 15 years; 68% female). A mean DAS28 of 4.87 ± 1.16 indicated moderate disease activity at baseline; disability was moderate to severe with a median (interquartile range) health assessment questionnaire score of 1.38 (0.80; 2.25). Median disease duration was 1 year (0.42; 7). Baseline values for weight and MAP were 73kg ± 14 and 98mmHg ± 12; median number of antihypertensive drugs was 0 (0; 0). After two years, patients on GCs gained mean 1.1kg (95%CI 0.5 to 1.8; p < 0.001; Table 1) more weight than patients in the control groups. Both groups increased MAP by 2-3mmHg, without difference between the groups (<0.4; 95% CI -3.0 to 2.2 mm Hg; p = 0.19; Table 1). The change in number of antihypertensive drugs was low and similar in both groups (Table 1). Results were consistent across sensitivity and subgroup analyses focusing on overweight or hypertensive patients, and when comparing GCs at 5mg/d with 7.5mg/d (data not shown).

Conclusion: We present robust evidence that low dose GCs, taken over two years for the treatment of RA, lead to about one additional kg of weight gain but do not cause changes in blood pressure.

The impact of synovitis of individual finger joints on grip force over the first five years in early rheumatoid arthritis

Keywords: Rheumatoid arthritis

M. Rydholm, A. Sharma, L. H. T. Jacobsen, C. Turesson, S. Skåne University Hospital, Department of Rheumatology, Malmö, Sweden; Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; Sahlgrenska Academy at Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: Rheumatoid arthritis (RA) has a major impact on hand function in many patients. Information on the contribution of individual joints to impaired grip strength may be helpful for guiding individualized management.

Objectives: The objective of this study was to investigate the relation between swelling and tenderness of individual finger joints and grip force over time in patients with early RA.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated and followed in a structured program, with follow-up evaluations after 1 and 5 years. All patients were examined by the same rheumatologist according to a structured protocol. Grip force (Newton) was measured using the electronic instrument Gripit (AB Detektör, Gothenburg, Sweden). Average grip force values of each hand were evaluated and compared to the expected values. Generalized estimating equations were used to adjust for repeated measurements of grip force as the dependent variable, we investigated whether time-varying synovitis of individual metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints were associated with reduced grip force over time. As wrist involvement, high erythrocyte sedimentation rate (ESR) and severe patient reported pain have been independently associated with reduced grip force in early RA (2), the analyses were adjusted for these parameters as time-varying covariates.

Results: A total of 215 patients with early RA (71% women; mean age 60 years) were investigated. The median symptom duration at inclusion was 7 months; interquartile range 5-10. Clinical synovitis was most frequently observed in MCP I and MCP II (60% at inclusion in both hands), and less in MCP IV and V (12-13% at baseline). Swelling of individual PIP joints was observed in 16-34% of patients at inclusion. Swollen joint counts (of 28 joints) decreased over time (median 7, interquartile range (IQR) 5-11 at diagnosis; median 4, IQR 4-7 after 5 years), and there was a parallel increase in grip force (mean 39% of expected for both hands at inclusion, 56% for the right hand and 55% for the left hand after 5 years). Synovitis of MCP I and MCP IV was significantly associated with reduced grip over time in both hands, with a similar finding for MCP V in the left hand only (Table 1), PIP synovitis had a lower impact on grip force (Table 1).

Table 1. Relation between synovitis of individual MCP and PIP joints and grip force (% of expected) over the first five years after diagnosis of RA; β (95% CI), adjusted for wrist synovitis, ESR and VAS pain.

MCP: Metacarpophalangeal joint
PIP: Proximal interphalangeal joint

Conclusion: MCP synovitis of the thumb is common in early RA, and a major contributor to reduced grip force over the first 5 years. Although less frequent, involvement of MCP IV and MCP V may also have a significant impact on hand function. Despite improvement, grip force was still impaired 5 years after RA diagnosis. This underlines the importance of both efficient treatment of synovitis and structured hand training in early RA.

Background: At time of Rheumatoid arthritis (RA) diagnosis, patients typically present with clinical arthritis of hand and foot-joints. It is unknown whether RA starts in hands or feet.

Objectives: To investigate this, we performed functional, clinical and imaging studies during progression from clinically suspect arthralgia (CSA) to RA. We also studied whether functional disabilities of hands/feet in CSA contribute to predicting RA-development.

Methods: 600 CSA-patients were followed for development of clinical inflammatory arthritis (IA) during a median follow-up of 25 months, of whom 99 developed IA. Functional disabilities were measured at baseline/4/12/24 months with the Health Assessment Questionnaire Disability-Index (HAQ); HAQ-items assessing hand- and foot-disabilities were selected. The course of disabilities towards IA-development (here considered as t=0) was depicted by increasing incidences and analysed using linear mixed models. To evaluate robustness of findings, tender hand/foot joints and subclinical joint-inflammation (measured with CE-1.5T MRI of hand/foot) were additionally studied. Associations between disabilities at CSA-presentation (here t=0) and future IA-development were studied using Cox-regression in the total CSA-population.

Results: During IA-development, hand-disabilities occurred earlier and more frequently than foot-disabilities. Despite both hand- and foot-disabilities rose significantly towards IA-development, hand-disabilities were more severe during this course (mean difference over time: 0.41 units,95%CI=0.28-0.55,p<0.001, on a range 0-3). Similar to functional disabilities, tender joints and subclinical joint-inflammation occurred earlier in the hands than feet (Figure 1). In the total CSA-population, a single HAQ-question on difficulties with dressing (hand-functioning) was independently predictive for IA-development: HR=2.2,95%CI:1.4-3.5,p<0.001.

Conclusion: Evaluation of functional disabilities, supported by clinical and imaging findings, revealed that joint involvement starts predominantly in the hands during RA-development. Additionally, a single question on dressing-difficulties adds value to risk stratification in CSA-patients and is easy to use in clinical practice.

Figure 1. Functional disabilities (A), tender joints (B) and subclinical joint-inflammation (C) towards IA-development occur earlier and more frequently in the hands than in the feet lines depict the increasing incidence of functional disabilities (HAQ), tender joints (physical examination) and subclinical joint-inflammation (MRI-detected) in the hands and feet prior to development of inflammatory arthritis. Abbreviations: HAQ= Health Assessment Questionnaire; IA= inflammatory arthritis.

DIFFICULT TO TREAT INFLAMMATORY ARTHRITIS: MAKING THE DEFINITION MORE PRECISE AND TIME FRAMED

Keywords: Outcome measures, Remission, Rheumatoid arthritis

1Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; 2Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; 3Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; 4Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; 5North Middlesex University Hospital, Rheumatology, London, United Kingdom; 6Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; 7Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt; 8Faculty of Medicine Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt; 9Faculty of Medicine - Minia University, Rheumatology and Rehabilitation, Minia, Egypt; 10Faculty of Medicine Kasr Al-Any, Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt; 11Faculty of Medicine, Fayoum University, Rheumatology and Rehabilitation, Fayoum, Egypt; 12Faculty of Medicine - Mansoura University, Rheumatology and Rehabilitation, Mansoura, Egypt; 13Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt

Background: Management of difficult to treat (D2T) inflammatory arthritis requires meticulous evaluation for the presence or absence of inflammation to support pharmacological and non-pharmacological management strategies. The challenge arises from the finding that D2T has been linked to a variety of characteristics. The EULAR Task Force has recently defined D2T rheumatoid arthritis as patients having persistency of symptoms and/or signs despite failure of at least two biological or targeted synthetic disease modifying anti-rheumatic drugs with different mechanisms of action. However, the proposed EULAR Task Force definition of D2T was based on just one assessment at one moment of time, during which flare up of the disease may not be reflective of the actual disease activity status.

Objectives: To address the unmet needs and derive a comprehensive, yet precise, approach to define the inflammatory arthritis patients who are “Difficult-to-Treat”.

Methods: Five key clinical questions including 20 domains were identified by core scientific committee. Literature Review team performed a systematic review to summarize evidence advocating the D2T definition, assessment and management, as well as benefits and harms of available pharmacologic and non-pharmacologic therapies. Subsequently, recommendations were formulated. The level of evidence was determined for each section using the Oxford Centre for Evidence-based Medicine (CEBM) system. A 3-round Delphi process was conducted. All rounds were conducted online. Consensus, consequently, to become a recommendation, would be achieved if at least 80% of participants reached agreement (score 7-9). A consensus was achieved on the direction and the strength of the recommendations.

Results: The work proposed an inclusive definition of D2T in inflammatory arthritis based on 4 pillars: “persistent inflammation that continues to cause significant burden despite standard treatment as perceived by the treating rheumatologist and/or the patient”. Two extra factors have been suggested to be added to the EULAR definition. These are “disease burden” and “time-frame” for the assessment of the disease activity status. “Continuous disease burden” has been defined as having difficulties in: Achieving treatment target, controlling disease progression, sustained elevation of the acute phase response over 3 months period attributed to the inflammatory joint disease, lack of functional restoration and poor quality of life despite good
symptomatic control, and treatment compliance due to: unacceptable tol-
erability or non-adherence or rejection of the treatment option. Time frame has been identified as: persistent joint inflammation (active/progressive dis-
ease) has been documented according to validated composite measures in-
cluding joint counts in 2-readings, 3-months apart. Level of agreement was high and in the range of 8.17-8.83.

Conclusion: this study revealed a consensus that time factor is vital to consider inflammatory arthritis as persistent, hence meet the difficult to treat definition. Adding the 'continuous disease burden has added another dimension to the management of O2T, advocating a more holistic approach
toward the patient rather than observing a patient through the prism of the index disease.

POS1084 EFFECT OF RHEUMATOID ARTHRITIS ON TOTAL KNEE ARTHROPLASTY

Keywords: Rheumatoid arthritis

W. Jeong 1, J. Kim 1. 1Jeju National University Hospital, Internal Medicine, Jeju, Korea, Rep. of (South Korea)

Background: According to the results of previous studies, it has been reported that rheumatoid arthritis (RA) patients receive total knee arthro-
plasty (TKA) at a younger age than osteoarthritis (OA) patients. However, studies on the effect of RA on TKA are still insufficient.

Objectives: We conducted this study to find out how RA affects primary TKA and revision arthroplasty.

Methods: The data of OA and RA patients who underwent primary TKA and revision arthroplasty at Jeju National University Hospital between March 2003 and December 2022 were retrospectively analyzed. To exclude the effect of other connective tissue diseases, patients with SLE, Sjogren's syndrome, polymyalgia rheumat-
ica, mixed connective tissue disease, undifferentiated connective tissue disease, Behçet's disease, systemic sclerosis, and vasculitis were excluded.

Results: A total of 5245 TKAs were performed, and the average age at primary TKA was 72.4 ± 6.4 years, and 2292 (85.7%) were female. When they were divided into OA group and RA group, RA knees were 159 (3.1%). The age at primary TKA in the RA group was significantly smaller (69.6 ± 6.8 vs 72.5 ± 6.4, p<0.001), and the female ratio was higher (91.9% vs 85.5%, p=0.031). Although the rate of revision surgery was not statistically significant, the RA group had more (5.6% vs 3.1%, p=0.111), and the period to revision tended to be shorter in the RA group (33.8 ± 49.2 months vs 67.7 ± 56.1 months, month, p=0.078). The cause of reoperation was not significantly different between the two groups, but the rate of infection was higher in the RA group (55.6% vs 43.7%, p<0.001), and reoperation due to loosening was more common in the OA group (46.2% vs 22.2%). There was no difference in other test values at the time of surgery, but in the RA group, ESR (43.8 ± 3.17 mm/h vs 26.6 ± 22.6 mm/h, P<0.001), CRP (1.8 ± 2.3 mg/dL vs. 0.8 ± 2.1 mg/dL, p<0.001) was significantly higher. The incidence of TKA was higher in the RA patients than OA patients (1436.2 per 100,000 Person-Years vs 1379.7 per 100,000 Person-Years). When comparing the risk of patients under-
going primary TKA during their lifetime by adjusting for gender, it was found that RA patients started receiving primary TKA at a younger age and had a signifi-
cantly higher risk of undergoing TKA (HR 1.48, 95% CI 1.263–1.733, P<0.001). As a result of logistic regression analysis, the increase in ESR (OR 10.2, 95% CI 1.01-103, P=0.001) and CRP (OR 1.09, 95% CI 1.01-1.17, P=0.021) at the time of primary TKA increase risk of revision arthroplasty, but RA did not.

Conclusion: Patients with RA have a higher risk of primary TKA and start primary TKA at a younger age, and the increased inflammation level at the time of primary TKA increase risk of revision arthroplasty, so it is recom-
mended to perform primary TKA after inflammation is controlled.

POS1085 INITIATION OF A JANUS KINASE INHIBITOR BEFORE AND AFTER THE SAFETY WARNINGS: CHANGES IN CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Registries, Comorbidities, Disease-modifying drug (DMARDs)

D. Huschke 1, P. Herzer 2, A. Zink 3, M. Feuchtenberger 4, A. Strangfeld 1,3, 1German Rheumatism Research Center Berlin, Epidemiology and Health Services Research Berlin, Germany; 2Rheumatologist, Private Practice, München, Germany; 3Scientific Advisory Board, RABBIT, Berlin, Germany; 4Rheumatologist, Innklinikum Burghausen Altötting, Germany; 5Charité, Universitätmedizin, Berlin, Germany

Background: In 2019, 2020 and 2021, the European and US-American reg-
ulatory agencies issued warnings about venous thromboembolism, major cardiovascular events and malignancy risks associated with the Janus
to kinase inhibitor (JAKi) tofacitinib and required changes in labelling.

Objectives: To investigate whether characteristics of patients with rheu-
matoid arthritis receiving a JAKi versus biologic therapy differed before and after the safety warnings.

Methods: Data from patients who started with any JAKi or biologics treatment in the German biologics register RABBIT between 01/2017 and 04/2022 were included. Multivariate logistic regression analyses were used to understand differ-
ces in characteristics of patients starting a JAKi treatment versus a biologic treatment in three annual cohorts: 2017 the year JAKis became available in Ger-
many, 2019 before the EMA safety warnings and 2021. In each year, only the first treatment episodes of each JAKi, TNF inhibitor, interleukin-6 inhibitor or B/T-cell targeted therapy were considered. Prior treatment episodes were possible. The logistic regressions were corrected for clustering at the patient level. In 2017, we included 549 JAKI versus 2510 biDMARD treatment episodes, in 2019 674 versus 2233 and in 2021 700 versus 1296 episodes.

Results: Patient characteristics at treatment start have changed over time. In 2017, compared to patients receiving a biologic, patients starting a JAKi had been treated with a higher number of therapies, had a higher (worse) physician reported health and were more likely to have comorbidities such as hypertension, coronary heart disease, diabetes, hyperlipoproteinaemia, thrombosis, malignancy or lymphoma. In 2019, patients initiating a JAKi therapy compared to a biologic were less likely to be women, had a worse physician reported health and were more likely to receive a dose of less than 10mg glucocorticoids than none. In 2021, after the safety warnings, compared to patients receiving a biologic, those who started a JAKi were older, had a worse physician reported health, had received a higher number of previous therapies, had poorer self-reported health and were less likely to receive a high dose of glucocorticoids. Although not significant, patients with comorbidities were less likely to receive a JAKi.
Conclusion: The analyses show that after the launch of JAKi treatment in 2017, comorbidities increased the likelihood to receive JAKis as a new treatment option. In 2021, patients with a high disease burden and with many other previous therapies were more likely to receive JAKis, but not those with comorbidities. This development shows that rheumatologists in Germany follow the safety recommendations and consider the patients' disease burden and risk factors when prescribing JAKis.

Efficacy of Pharmacological Interventions: A Systematic Review Informing the 2023 EULAR Recommendations for the Management of Fatigue in People with Inflammatory Rheumatic and Musculoskeletal Diseases

Keywords: Patient reported outcomes; Systematic review; bDMARD

B. Farisogullari, E. Santos, E. Dures, P. Machado

Background: There is evidence that pharmacological interventions, including biologic therapies, can improve inflammation, disease activity and function in inflammatory rheumatic and musculoskeletal diseases (I-RMDs), and fatigue has increasingly been included as a secondary outcome of I-RMDs clinical trials. However, no systematic review (SR) has established the evidence for the pharmacological management of fatigue in people with I-RMD [1,2].

Objectives: To identify the best evidence on the efficacy of pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with I-RMD.

Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, CINAHL Complete, PEDro, OTseeker and PsycINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.

Results: From a total of 4,150 records, 454 were selected for full-text review, 178 fulfilled the inclusion criteria, and 19 RCTs were included in meta-analyses. Adalimumab was superior to placebo in reducing fatigue at 52 and 12 weeks (wk) in rheumatoid arthritis (RA) (mean difference [MD]=-2.25, p<0.03; MD=-3.03, p<0.01; respectively) and psoriatic arthritis (MD=-3.16, p=0.26). Golimumab (24 wk: MD=-5.27, p<0.001), baricitinib (24 wk: MD=-4.06, p<0.001), tofacitinib (24 wk: MD=-3.15, p=0.001), tocilizumab (24 wk: MD=-3.69, p=0.001) and tofacitinib (12 wk: MD=-4.44, p<0.001) were also superior to placebo in reducing fatigue in RA. A dose-effect relationship was observed for sarilumab, tocilizumab and tofacitinib. In spondyloarthritis, secukinumab was superior to placebo in reducing fatigue at 16 wk (MD=-4.15, p<0.001), with a dose-effect relationship also observed (Figure 1). The narrative results of the RCTs not included in the meta-analysis indicated that several other pharmacological interventions were efficacious in reducing fatigue, with reassuring safety results.

Conclusion: Pharmacological interventions are efficacious and safe for the management of fatigue in people with I-RMD.

The Patient-Perspective and Feasibility of Home Finger Prick Testing to Complement and Facilitate Large Scale Digital Data Collection

Keywords: Health services research, Inflammatory arthritis; Patient reported outcomes

Y. Besten, L. Boekel, M. Steenhuis, F. Hooijberg, M. Leeuw, S. Atiqi, E. Vogelzang, J. Keijzer, O. Cristianawati, S. Keijzer, F. Loef, M. Gerritsen, S. Tas, M. Nummohamed, T. Rispens, G. Wolbink, Reade. Locatie Dr. van Bremenstraat, Rheumatology, Amsterdam, Netherlands; 2Sanquin Research and Landsteiner Laboratory, Immunopathology, Amsterdam, Netherlands; 3Amsterdam UMC, locatie AMC, Medical Microbiology and Infection Control, Amsterdam, Netherlands; 4Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 5Amsterdam UMC, locatie VUMc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands.

Background: Previous studies have shown that using a finger prick as the primary method for blood withdrawal is an efficient way to collect blood samples remotely, and data on blood levels from a finger prick are directly comparable to those obtained by a venepuncture. During the COVID-19 pandemic, we therefore complemented our large digital research platform with serum collection via a home finger prick testing in order to collect samples without the need of visits to a hospital. This repeatedly enabled us to rapidly answer new and relevant clinical research questions about COVID-19, thereby showing the potential of the finger prick for research purposes. However, the use of finger pricks in a research or clinical practice setting is still uncommon, and not yet tested on a large scale. In addition, there is limited data on peoples' willingness and ability to successfully use the finger prick at home, especially in patients with inflammatory rheumatic diseases (iRD) who may have impaired hand function.

Objectives: To investigate the feasibility of finger prick testing in combination with a digital research platform by evaluating the success rate and patients' perspective towards the use of the finger prick.

Methods: Data were collected from an ongoing prospective cohort study including patients with iRD from the Amsterdam Rheumatology & Immunology Center and healthy controls. Serum samples were collected up to eight times during follow-up via blood withdrawal by venepuncture at the local research institute or via a finger prick that could be performed at home. For the latter option, participants were instructed to collect three drops of blood, which would yield approximately 40-80 µL of serum after clotting. All study participants were questioned about their preference for a particular sampling method for individual healthcare and for scientific research. Participants who received a finger prick test before June 26, 2021, were asked to complete a digital evaluation questionnaire of the finger prick after their attempt. The finger prick was defined as failed when less than 10 µL of serum could be recovered from the collection device, or if no sample was returned to the laboratory and participants indicated in the questionnaires that they did not succeed in collecting the required amount of serum.

Results: A total of 3080 patients with iRD and 1102 healthy controls were included in the study. Of these, 2135 (69%) patients and 899 (82%) controls attempted to execute at least one finger prick, and 1439 (67%) patients and 712 (21%) controls executed multiple finger pricks. The first finger prick was successfully done by 92% (CI 90 – 93) of iRD patients, 94% (CI 92 – 95) of healthy controls, 93% (CI: 92 – 94) of all participants aged 70 years or younger, and 89% (CI 86 – 92) of all participants aged above 70 years (Table 1). Sex did not impact
these success rates. Repeated failure occurred in 11 of 1439 (0.8%) patients and 4 of 712 (0.6%) controls. The two most common reasons for perceived failure of the finger prick were related to insufficient blood yield when applying the finger prick to the ear. Additionally, 77% of patients and 85% of controls were willing to perform a finger prick for individual healthcare compared to scientific research; 31% of patients and 61% of controls were willing to perform a finger prick for scientific research compared to 19% of patients and 39% of controls for healthcare. The most important reason for this was lower confidence in the execution and laboratory measurements when blood was drawn via a venepuncture compared to a finger prick.

Conclusion: In this study, we demonstrated that the vast majority of participants, among which elderly and patients of whom hand function may be impaired by an underlying rheumatic disease, were able to successfully draw the required amount of blood for serological analyses. This shows that the finger prick testing is suitable for a high-throughput implementation to monitor patients remotely, which will likely contribute to improving the efficiency and cost-effectiveness of both healthcare and scientific research.

Rheumatoid arthritis - comorbidity and clinical aspects

Keywords: Mental health, Inflammatory arthritis, Patient reported outcomes

L. Zhao1, J. Galloway2, J. Ledingham3, S. Gallagher4, N. Garnavos4, P. Amlani-Hatcher5, N. Wilson2, L. Carpenter2, K. Bannister2, S. Norton5,6,1. King’s College London, Institute of Psychiatry, Psychology, and Neuroscience, London, United Kingdom; 2King’s College London, Center for Rheumatic Diseases, London, United Kingdom; 3Portsmouth Hospitals University NHS Trust, Rheumatology Department, Portsmouth, United Kingdom; 4British Society for Rheumatology; 5National Early Inflammatory Arthritis Audit (NEIAA), London, United Kingdom; 6King’s College London, Department of Psychology, London, United Kingdom; 7King’s College London, Wolfson Centre for Age-Related Diseases, London, United Kingdom

Background: In inflammatory arthritis patients, the concomitant decline of their mental wellbeing is an increasing concern [1,2]. It is important to not only describe the trajectory of psychological distress in early disease stages, but also understand which clinical outcome measures are most associated with these changes.

Objectives: Using data from the National Early Inflammatory Arthritis Audit (NEIAA), we assessed trends in psychological wellbeing over 12 months after initial diagnosis and mapped these against clinical outcomes to identify significant associations.

Methods: NEIAA collects data from patients referred with suspected early inflammatory arthritis in rheumatology services in England and Wales. We used data provided by 20,472 patients eligible for follow-up (diagnosis of inflammatory arthritis) between May 1st, 2018, and April 1st, 2022. Data items included baseline demographics e.g., age and gender, and clinical variables e.g., rheumatic disease comorbidity index (RDCI), DAS28, and patient reported outcomes. Psychological distress was measured by the sum score of Patient Health Questionnaire Anxiety and Depression Screener (PHQ4ADS). Using mixed effects regression models, we analysed the co-variability of PHQ4ADS with demographic factors and clinical outcomes over 12 months. Time was included as a dummy-coded covariant.

Results: The analysis included 36% of patients (7378 out of 20,472) who completed the baseline patient outcome survey. In this cohort, PHQ4ADS scores decreased from a baseline average of 4.7 (CI: [4.6, 4.8]) to 2.62 (CI: [2.5, 2.8]) at 12 months post-diagnosis. The proportion of patients screening positive decreased from 50.0% (CI: [48.9, 51.1]) at baseline to 23.8% (CI: [21.8, 25.9]) at 12 months. At baseline, psychological distress correlated significantly with age, gender, ethnicity, RDCI, prior depression diagnosis, and baseline DAS28 (Figure 1).

Conclusion: In this early inflammatory arthritis cohort, mental health burden was high. Age, gender, ethnicity, RDCI, prior depression diagnosis and baseline DAS28 significantly correlated with psychological distress at baseline. Supporting mental health should be a focus of clinical care for this population and it may be beneficial to use an approach that is culturally valid for non-white patients and accounts for multiraciality.

POS1096 IMPLEMENTATION OF QUALITY STANDARDS FOR HEALTH CARE OF PATIENTS WITH RHEUMATOID ARTHRITIS: FIRST RESULTS FROM THE NATIONAL DATABASE OF THE GERMAN COLLABORATIVE ARTHRITIS CENTRES

Keywords: Health services research, Rheumatoid arthritis, Quality of care

Figure 1. Changes in psychological distress correlated with age, gender, ethnicity, RDCI, prior depression diagnosis, and baseline DAS28.
Background: Despite the establishment of national and international recommendations for the management of patients with rheumatoid arthritis (RA), reme- diable deficits in the quality of care (QoC) still exist. On behalf of the German Society for Rheumatology, with participation of the patient organization Deutsche Rheuma-Liga, eight Quality standards (QS) have been developed to improve the QoC in Germany. The QS can be used to determine and quantitative gaps in QoC in respect to time to diagnosis, use of glucocorticoids, rates of remission and impairments in physical function [1].

Objectives: To quantify gaps in QoC based on five QS in patients with RA for whom data from the National Database of the German Collaborative Arthritis Centres (NDB) exists.

Methods: In 2020, 4863 patients with RA from 12 Rheumatology centres were followed in the NDB. Five QS were reviewed: (Q5) How often was RA diagnosed within 8 weeks of symptom onset? (QSS) How many patients in remission? (QSH) How many patients are in glucocorticoid-free remission? (QSC) How many patients who were not in remission had their medication adjusted? (Q5S) How many patients with impairments in physical function received physiotherapy, functional training, and/or rehabilitation? Remission was investigated both by DAS28 and by CDAI cut-offs. Impairments in physical function were assessed with the FFBH (≥70% of full function). Switches, additions, or dose increases of disease-modifying antirheumatic drug (DMARD) were considered adjustment of medication. Individual components of the DAS28 are reported to determine reasons for not achieving remission.

Results: Fulfillment of QS (Figure 1) was investigated in 4863 patients (Table 1). In 2020, 76 patients had their first contact to rheumatologist and 30 were seen by a rheumatologist within 8 weeks (36%). Of 61 patients with available diagnosis date, 25 (41%) were diagnosed within 8 weeks. 1523 of 3410 patients with available DAS28 were in DAS28 remission (45%) and 933 of 4023 patients with available CDAI were in CDAI remission (23%). 1155 of 1520 patients in DAS28 remission and 789 of 930 RA patients in CDAI remission were glucocorticoid-free (76% vs. 85%). 373 of 1676 patients who were not in DAS28 remission had adjustment of medication (22%). Patients without therapy adjustment had fewer clinical signs of inflammatory activity (SJC 1.3 vs. 2.6, TJC 2.6 vs. 3.7, ESR 25.7 vs. 27.4, Physician global 1.8 vs. 2.8). Patient disease activity 4.1 vs. 4.8) compared to patients with adjustment of medication. 68 of 149 patients with high disease activity (DAS28>5.1) had adjustment of medication (46%). 377 of 772 patients with impairments in physical function and information on physiotherapy received physiotherapy (49%), 32 of 767 patients with data on functional training received functional training (4%) and 117 of 1175 patients with data on rehabilitation received rehabilitation (10%).

Conclusion: With the new QS, QoC of patients with RA can be measured in a standardized form. While some results reflect high quality of care, other QSs point to opportunities for improvement. The implementation of the QS enables both a comparative evaluation at facility level and a general rheumatology health-care outcome. This will help to optimize the QoC for patients with RA in Germany.

Background: Engaging in regular physical activity (PA) is important in maintaining health and increasing the overall quality of life for patients living with chronic inflammatory rheumatic diseases (CIRD). It is assumed that patients with CIRD reports low levels of physical activity. In the era of evidence-based medicine few studies compare PA levels and its predictors between patient with CIRD and healthy control.

Objectives: we aim to investigate PA levels of patients with CIRD, to examine predictors of PA and furthermore compare findings to healthy control.

Methods: A cross-sectional study was performed among patients with CIRD Aged between 18 and 65 years old who visited the outpatient clinic between April 2022 and October 2022. The diagnosis of spondyloarthritasis was based on ASAS criteria and the diagnosis of rheumatoid arthritis was based on ACR/EULAR 2010 criteria. Healthy controls were recruited in a specialized consultation. Socio-demographic findings were collected. Patients were assessed for pain and disease activity using visual analog scale (VAS) DAS28 CRP and ASDAS CRP. Physical activity levels were assessed using the international physical activity questionnaire (IPAQ-SF). Furthermore, all participants underwent screening for anxiety and depressive disorders using Patient health questionnaire (PHQ-9) and General anxiety disorder (GAD-7) respectively.

Results: The final study sample was made up of 172 patients (92 RA, 65 SpA and 15 Undifferentiated CIRD) and 159 healthy controls.

POS1093

WHO ARE THE PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE IN NEED TO SPECIALISED MULTIDISCIPLINARY REHABILITATION?

Keywords: Rehabilitation, Non-pharmacological interventions

E. Besada1, 2, 3, Fysikalskmedisinsk avdeling, UNT Tromsø, Tromsø, Norway; 2Medisinsk avdeling Kirkenes, Finnmarkssykehuset, Kirkenes, Norway; 3Institutt for klinisk medisin, UiT Norges arktiske universitet, Tromsø, Norway

In patients with CIRD uni and multivariate analysis showed no association between PA levels and disease related variables: Disease activity(OR (95%CI) = -0.032 (-0.160, 0.095); p=0.61), disease duration(OR (95%CI) = -0.013 (-0.028, 0.003); p=0.111) and comorbidities(OR (95%CI) = -0.013 (-0.109, 0.083); p=0.794) on the contrary PA levels were negatively associated with depression (OR (95%CI) = -0.011 (-0.021, -0.002); p=0.021) in healthy controls uni and multivariate analysis showed that PA levels were negatively associated with age (OR (95%CI) = -0.013 (0.004, 0.020; p=0.037), BMI (OR (95%CI) = -0.029 (0.051, 0.006; p=0.033) and depression (OR (95%CI) = -0.029 (-0.049, -0.009; p=0.004)).

Conclusion: Our study shows that patients with CIRD reports significantly low levels of PA and high level of SB compare to healthy controls. The unexpected finding in our study is that low levels of PA in patients with CRID were not associated with disease activity nor disease duration. Depressive disorders are an important predictor of physical inactivity and sedentary behavior regardless of the presence of CRID. Depressive disorders are common among patients with CRID. Screening for depression and treating in time is essential to help overcome sedentary behavior in our patient population.

DOI: 10.1136/annrheumdis-2023-eular.1873
Background: Patients with inflammatory rheumatic disease, while receiving highly effective disease-modifying antirheumatic drugs, are still referred to multidisciplinary rehabilitation in specialised centres. Although multidisciplinary rehabilitation only have small and short-term improvements in patients' outcome, it could benefit patients with specific disability and rehabilitation needs, indicating a more complicated disease [1].

Objectives: In order to identify the specific rehabilitation needs of patients with inflammatory rheumatic disease, it is of paramount importance to describe their clinical characteristics. The present study includes all patients with inflammatory rheumatic disease who were referred to multidisciplinary rehabilitation in Northern Norway between 2018 and 2021.

Methods: In Norway, the cost of multidisciplinary rehabilitation in specialised centres is covered by the national welfare system. However patients must be referred by a physician and the referral approved by the regional assessment office (rehabilitation regional vurderingsenhet) at the University Hospital of North Norway. All patients referred to multidisciplinary rehabilitation were included in this longitudinal study; the study was retrospective from January 1st 2018 to 31st December 2018 and afterwards prospective to June 10th 2021. Data were extracted from referrals and hospital discharge summaries. Age, gender, diagnosis, county and municipality, referring physicians were collected in all patients. Major symptoms and associated diseases were later included in the study.

Results: 786 patients out of 1028 referrals were referred to multidisciplinary rehabilitation during the study period. The referral rate was 0.39 and 0.56/1000 persons/year for respectively the counties of Nordland and Troms-Finnmark. Patients’ mean age was 54 and 76 % were women. 43 % of all patients were first time referral. 56 % had spondyloarthrits, 23 % rheumatoid arthritis, 15 % connective tissue disease and 3.3 % vasculitis including polymyalgia rheumatica. The most common associated diseases were osteoarthritis and obesity, respectively in 36 and 31 % (Table 1). 41 % complained of fatigue and 38 % had diffuse pain.

Conclusion: In Northern Norway, the referral rate to multidisciplinary rehabilitation is 0.47/1000 persons/year. The prototypical patient referred to multidisciplinary rehabilitation is a woman in her sixth decade with spondyloarthritis, often complaining of fatigue and diffuse pain. Although these patients have seldom major physical disability, they are mostly in need for coping strategies regarding fatigue and chronic pain.

THE EULAR TOOL IS SUPERIOR TO A GENERIC TOOL IN THE ASSESSMENT OF MUSCULOSKELETAL ULTRASOUND COMPETENCE: A VALIDITY STUDY

Keywords: Ultrasound, Education

S. M. D. Carstensen1,2, S. A. Just1, M. Pfeiffer-Jensen3, M. Østergaard1,2, L. Konge2,3, L. Terslev1,3 Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Rigshospitalet, Glostrup, Denmark; 2Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, University Hospital of Copenhagen, Rigshospitalet, Glostrup, Denmark; 3Section of Rheumatology, Department of Medicine, Svendborg Hospital, Odense University Hospital, Odense, Denmark; 4Copenhagen Academy for Medical Education and Simulation, The Capital Region of Denmark, Copenhagen, Denmark

Background: Musculoskeletal ultrasound (USUS) is a widely implemented tool in rheumatological routine care. It has been established which competencies are relevant for rheumatologists[1], and competency levels have already been developed within European League Against Rheumatism (EULAR)[2] and European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB)[3]. Furthermore, the content and conduct of MSUS courses have been published[2]. Thus, the only component missing is an objective assessment tool supported by a contemporary validity framework to determine when residents have acquired the competencies relevant for independent practice[1].

A generic assessment tool for the assessment of ultrasound competence, The Objective Structured Assessment of Ultrasound skills (OSAUS)[4], has been developed and is already used in clinical practice in several other medical fields[5,6]. EULAR has developed another assessment tool specific for MSUS. Although both OSAUS and the EULAR tool are consensus-based, the tools' reliability and their discriminatory ability have not been explored.

Objectives: To explore the validity of the generic OSAUS tool and the EULAR tool for the assessment of MSUS operator performance. Moreover, to examine the optimal number of cases and raters needed to ensure a reliable assessment of residents.

Methods: We included 30 physicians, representing MSUS novices, intermediates, and experts. Validity evidence was gathered using the gold standard contemporary framework of Messick[8]. All participants performed MSUS examinations of four joint areas: the wrist, fingers, ankle, and shoulder on the same patient with rheumatoid arthritis. All performances were video recorded and subsequently assessed in completely random order by two blind raters using either the OSAUS assessment tool and then one month after, followed by new randomization of the videos, the EULAR tool.

Results: A total of 120 videos were assessed twice by two assessors. The inter-rater reliability was high for both tools: 0.807 (OSAUS) versus 0.848 (EULAR), and both tools demonstrated excellent inter-case reliability of 0.970 (OSAUS) versus 0.964 (EULAR). The ability to discriminate between different experience levels and MSUS performance was significant (p <0.001) for both the OSAUS and the EULAR tool. Moreover, by conducting a series of Decision-studies, we estimated the optimal number of cases and raters needed to ensure a reliable assessment (generalizability coefficient >0.8). A reliable assessment could be reached by using either one rater and three cases or two raters and one case (Figure 1).

Figure 1. Number of raters and cases needed to make a reliable assessment of MSUS competencies
Conclusion: MSUS operator competences can be assessed in a reliable and valid way using either the OSAUS or the EULAR assessment tool, thereby allowing a uniform competency-based MSUS education in the future. Although both tools demonstrated high inter-rater reliability, the EULAR tool was superior to OSAUS. Using the EULAR tool in clinical practice will allow a single assessor to provide a reliable MSUS assessment of the trainee by observing only two different MSUS examinations.

E-LEARNING AND PRACTICAL PERFORMANCE IN MUSCULOSKELETAL ULTRASOUND - A MULTICENTER RANDOMIZED STUDY

**Keywords:** Education, Ultrasound, Randomized control trial

S. M. D. Carstensen1,2, S. A. Just3, M. Velander3, L. Konge2,4, M. Slusarczyk Hubel5, T. R. Savarimuthu6, M. Pfeiffer-Jensen7,1, M. Østergaard1,2, L. Terslev1,2,1 Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, University Hospital of Copenhagen, Rigshospitalet, Glostrup, Denmark; 2Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; 3Section of Rheumatology, Department of Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark; 4Copenhagen Academy for Medical Education and Simulation, The Capital Region of Denmark, Copenhagen, Denmark; 5SDU Robotics, The Maersk Mc Kinney Moller Institute, University of Southern Denmark, Odense, Denmark

**Background:** The COVID-19 pandemic has forced a change in the teaching approach when educating physicians. Several training programs have been digitally transformed, including complex procedures such as ultrasound [1]. Recent studies have suggested the possibilities for practicing theoretical and practical ultrasound skills using online platforms, e.g., e-learning [2]. Even though the effect of e-learning on theoretical knowledge is unquestionable, the impact on practical skills is unknown. Thus, it is essential to examine the effect of e-learning on the development of practical skills.

**Objectives:** To examine the effect of pre-course e-learning on residents’ practical performance in musculoskeletal ultrasound (MSUS). Moreover, to examine the effect of pre-course e-learning on residents’ satisfaction with the following face-to-face MSUS course.

**Methods:** We designed a multi-center randomized controlled study following the CONSORT statement. Residents with no or little MSUS experience were randomized to either an e-learning group or a traditional group. One week before a 2-day face-to-face MSUS course, the e-learning group received access to an interactive platform consisting of online lectures, assignments, and practical instruction videos aligned with the content of the following course. The traditional group only received standard pre-course information (program, venue, and time). All participants performed a pre- and post-course practical MSUS examination and were assessed by two individual raters, blinded to the group allocation, using the validated Objective Structured Assessment of Ultrasound skills (OSAUS) tool. Finally, the participants filled out a subjective satisfaction questionnaire, the Intrinsic Motivation Inventory (IMI).

**Results:** Twenty-eight participants completed the study. There were no statistically significant differences in the pre- or post-course practical MSUS performance between the e-learning group and the traditional group: the mean pre-course OSAUS score (±SD) in the e-learning group was 5.4±3.7 compared to 5.2±2.4 in the traditional group, p=0.8, whereas the post-course OSAUS score in the e-learning group was 11.5±2.8 compared to 10.9±2.4 in the traditional group, p=0.8 (Figure 1). Figure 1. The effect of e-learning on novices’ practical MSUS performance before and after the face-to-face course. There was a significant difference between the mean pre- and post-course scores (p<0.001) for both groups. The OSAUS assessment tool demonstrated excellent inter-rater reliability (ICC=0.84). There were no significant differences between the groups regarding their subjective satisfaction with the course measured by the IMI score.

**Conclusion:** We found no significant impact of pre-course e-learning on novices’ acquisition of practical MSUS skills or on trainees’ satisfaction with the course. Hands-on training is of utmost importance and improves MSUS performance significantly. The OSAUS assessment tool is an applicable tool for the assessment of trainees’ MSUS competences and demonstrated excellent inter-rater reliability.

**POST1096**

ASSESSMENT OF PERCEPTION OF BENEFITS AND BARRIERS TO EXERCISE PARTICIPATION AMONG PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY INDIVIDUALS: A CASE CONTROL STUDY

**Keywords:** inflammatory arthritides, Education, Rehabilitation

A. Adnine1, F. Z. Taik1, N. Takhrifa1, F. Z. Aharrane2, N. Sob3, M. Fourtassi2, F. E. Abourazzak1, 1Abdelmalek Essaïdi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, TANGIER, Morocco; 2Abdelmalek Essaïdi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco

**Background:** Benefits of regular physical activity (PA) are well known and well publicized. Despite the many benefits of PA, patients with chronic inflammatory rheumatic diseases (CIRD) report low levels of PA and engage more in sedentary behavior.

**Objectives:** To examine the perception levels of benefits and barriers to exercise participation among patients with CIRD and healthy individuals and examine the predictors of poor perception levels.

**Methods:** A cross-sectional study was performed among patients with CIRD aged between 18 and 65 years old who visited the outpatient clinic. Healthy controls were recruited in a specialized consultation. Socio-demographic and clinical findings were collected. Physical activity levels were assessed using (IPAQ). Perceived benefits and barriers to exercise scale (PBBS) was used to assess the perception of patients and healthy controls toward exercise. Furthermore, all participants underwent screening for anxiety and depressive disorders using (PHQ-9) and (GAD-7) respectively.

**Results:** 172 patients were enrolled in the study (92 RA, 65 SpA and 15 Undifferentiated CIRD) and 159 healthy controls.
RheumACaN was a 1 year rolling programme with face to face discovery day meetings sharing best practice, teaching and discussion on local referral pathways, guidelines and interventions. In between the faces to faces sessions there was active learning through virtual mentoring. Participants completed action learning sets, case management practicals. The outcome was measured through metrics in the NEIAA, referral patterns and feedback from participants.

Results: RheumACaN was attended by 80 participants over 2 cohorts in 2021-2022 including general practitioners (GPs), community musculoskeletal (MSK) physiotherapists and first contact practitioners (FCPs). Prior to RheumACaN, the number and percentage of patients with suspected early inflammatory arthritis (EIA) referred to a specialist clinic within three working days which is a measure of primary care performance was 109/312 (32%) in 2018/19, 190/334 (57%) in 2019/20, 45/86 (52%) in 2020/21. Post RheumACaN, this increased to 140/201 (70%) in 2021/22. The national average for this metric was 47% in 2019/20 and 54% in 2021/22. Feedback from 2 cohorts was 100% scored 5/5 (excellent) for how well the purpose of the programme was communicated, 100% scored 5/5 for how organised and easy to follow the programme was, 98% scored 5/5 for how engaged the presenters were. All participants responded that they had learned from the programme and this would change their practice. Narrative feedback included: “Very interesting - diagnosis and management, and when to refer onwards, very clear”, “Really helpful for future referrals, good tips what to look out for”, “Clear criteria and management (onward referral)” “Enjoy discussing the cases and getting feedback, useful to hear other cases”, “Great having group discussion, learned so much”; “Fantastic afternoon, energising, positive, lots of new ideas/approaches”.

Conclusion: We created RheumACaN, a knowledge-sharing model to bring together clinicians from primary and secondary care for a robust, holistic approach to manage rheumatic diseases. Similar models such as project ECHO with the hub and spoke model of moving knowledge not people have been used[1]. Our collective understanding of how to disseminate and implement best practices across diverse disciplines resulted in the rapid increase of early referrals of inflammatory arthritis from primary care in our centre which is now above the national average in the UK. New referral quality and outcomes are continuously reviewed with an annual audit to assess impact in line with the NEIAA. RheumACaN has also a train the trainer ethos with participants in Cohort 1 coming back to share and teach Cohort 2. Cohort 1 graduates have also been doing peer to peer teaching sessions to help spread and ensure sustainability. This continuous loop of learning, mentoring and peer support makes this a unique programme, with a long-lasting impact far beyond that of a webinar, e-learning course or seminar, with knowledge that is tested and refined through a local lens.

Spondyloarthritis - treatment

Objectives: RheumACaN aims to build confidence in primary care to refer and manage patients with inflammatory arthritis (RA, PsA, AxSpA) as well as other rheumatic diseases. Through integration of pathways from primary to secondary care, RheumACaN aims to reduce delays to diagnosis, improve referral from primary care and enhance management of patients.

Methods: RheumACaN was a 1 year rolling programme with face to face discovery day meetings sharing best practice, teaching and discussion on local referral pathways, guidelines and interventions. In between the faces to faces sessions there was active learning through virtual mentoring. Participants completed action learning sets, case management practicals. The outcome was measured through metrics in the NEIAA, referral patterns and feedback from participants.

**Table 1. Efficacy at Wk 52**

**Mean (SE), unless stated**

**References:**

experience loss of response in the long term and maintenance of response is an internationally recommended treatment target.[1] Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A. BKZ has demonstrated consistent and sustained clinical efficacy to Week (Wk) 52 in pts across the full spectrum of axSpA in the phase 3 studies BE MOBILE 1 and 2.[2]

**Objectives:** To report the maintenance of stringent clinical responses through one year of treatment with BKZ in pts with non-radiographic axSpA (nr-axSpA) and radiographic-axSpA (r-axSpA, i.e.,ankylosing spondylitis)[3] in phase 3 studies.

**Methods:** In BE MOBILE 1 (NCT03928704; nr-axSpA; pts met ASAS criteria for axSpA) and BE MOBILE 2 (NCT03928743; r-axSpA; pts fulfilled ASAS and modified New York criteria for r-axSpA), pts were randomised to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO) to Wk 16. From Wks 16–52, all pts received BKZ 160 mg Q4W.[4,5] ASAS40 and ASDAS LDA (<2.1 in ASAS40 and <1.3 in ASDAS ID) responders to Wk 52 were assessed among BKZ-randomised pts who responded at Wk 16. Missing ASDAS40 data were imputed using non-responder imputation (mediation), and multiple imputation (MI) was used for missing ASDAS data. MI was based on Markov Chain Monte Carlo (for intermittent missing data) followed by monotone regression (for monotone missing data). Observed case (OC) data are also reported. Wk 16 and Wk 52 responder rates for all BKZ-randomised pts are included in context (NRI or MI). The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for BE MOBILE 1 and 2, including pts who switched from PBO to BKZ at Wk 16.

**Results:** A total of 128 and 221 pts were randomised to BKZ 160 mg Q4W in BE MOBILE 1 and 2, respectively. At Wk 16, 47.7% and 44.8% of these pts achieved the primary endpoint, ASAS40, and this increased to 60.9% and 58.4% at Wk 52 (NRI, Figure 1). Of pts that achieved ASAS40 at Wk 16, 82.0% and 83.8% maintained this response at Wk 52 (NRI, Figure 1). ASDAS LDA was achieved by 46.1% and 44.8% of BKZ-randomised pts at Wk 16 of BE MOBILE 1 and 2, respectively; this increased to 61.6% and 57.1% at Wk 52 (MI, Figure 1). Of pts that achieved ASDAS LDA at Wk 16, 88.5% and 88.4% maintained this response at Wk 52 (MI, Figure 1). At Wk 16 of BE MOBILE 1 and 2, ASDAS ID was achieved by 18.8% and 16.4% of BKZ-randomised pts, respectively; and this increased to 25.2% and 23.4% at Wk 52 (MI). Among Wk 16 ASDAS ID responders, ASDAS ID was maintained by 79.2% and 75.1% at Wk 24, 85.3% and 71.7% at Wk 36, and 88.0% and 58.7% at Wk 52 (MI). To Wk 52 of BE MOBILE 1 and 2, 183/244 (75.0%) and 249/330 (75.5%) pts reported ≤1 TEAEs whilst receiving BKZ, respectively; 9 (3.7%) and 20 (6.1%) reported serious TEAEs.

**Conclusion:** Dual inhibition of IL-17F and IL-17A with BKZ provided robust maintenance of stringent clinical responses from Wk 16 to Wk 52 across the full axSpA disease spectrum. This is consistent with previously reported observations of BKZ treatment over three years in pts with nr-axSpA in the phase 2b study BE AGILE and its open-label extension.[6]

**Objectives:** To report achievement of LDA, as assessed by either ASDAS <2.1, BASDAI <4, or both, to Wk 52 with BKZ across the spectrum of axSpA in two phase 3 studies.

**Methods:** BE MOBILE 1 (NCT03928704) and BE MOBILE 2 (NCT03928743) each comprised a 16-wk placebo (PBO)-controlled and 36-wk maintenance period.[5] Pts with nr-axSpA in BE MOBILE 1 met Assessment of SpondyloArthritis International Society (ASAS) classification criteria and had objective inflammation as assessed by MRI and/or elevated C-reactive protein. Pts with r-axSpA included in BE MOBILE 2 met modified New York criteria and also fulfilled ASAS classification criteria. All pts had active disease (BASDAI ≥4 and spinal pain ≥4 as per BASDAI item 2) at baseline. Pts were randomised to subcutaneous BKZ 160 mg every 4 wks (Q4W) or PBO; all pts received BKZ 160 mg Q4W from Wk 16 onwards.[5] The PBO arm is therefore referred to as PBO up to Wk 16, and PBO/BKZ at later timepoints. Here, we present the proportion of pts achieving LDA to Wk 52, as defined by either ASDAS <2.1, BASDAI <4, or both, using non-responder imputation.

**Results:** A total of 254 pts with nr-axSpA (BKZ: 128, PBO: 126) and 332 with r-axSpA (BKZ: 221, PBO: 111) were randomised. Most pts had high ASDAS (≥2.1–3.5) or very high (ASDAS >3.5) disease activity at baseline (nr-axSpA: BKZ: 99.2%, PBO: 97.6%; r-axSpA: BKZ: 98.6%, PBO: 100%). In pts with nr-axSpA, a greater proportion of BKZ vs PBO-treated pts achieved LDA at Wk 16 according to ASDAS <2.1 (BKZ: 46.1%, PBO: 19.6%), BASDAI <4 (BKZ: 52.3%, PBO: 31.7%), and both (BKZ: 43.8%, PBO: 19.0%). Separation from PBO was apparent from post-first baseline assessment for ASDAS <2.1 and both ASDAS <2.1 and BASDAI <4 (Figure 1). Results were similar for pts with r-axSpA (Figure 1). Across continuous BKZ-treated pts and PBO/BKZ switchers, achievement of LDA, according to ASDAS <2.1, BASDAI <4, and both, was sustained or improved in both studies to Wk 52 (Figure 1). Proportion of pts achieving BASDAI <4 was consistently higher compared with achievement of ASDAS <2.1, regardless of treatment arm.

**Conclusion:** Across the full axSpA disease spectrum, dual inhibition of IL-17A and IL-17F with BKZ resulted in rapid achievement of LDA vs PBO to Wk 16, as assessed by ASDAS <2.1, BASDAI <4, or both. Proportion of pts achieving LDA increased to Wk 52. These data suggest that ASDAS <2.1 is a more stringent criterion for LDA than BASDAI <4, and the majority of pts who achieved ASDAS <2.1 also achieved BASDAI <4. This is relevant for the consideration of BKZ in the context of a potential treat-to-target approach for pts with axSpA in daily practice.

**Doi:** 10.1136/annrheumdis-2023-eular.833
Results: This pooled analysis included 505 TNFi-naïve and 81 TNFi-IR pts. 302/505 (59.8%) TNFi-naïve and 47/81 (58.0%) TNFi-IR pts were randomized to BKZ. At Wk 16, the proportion of pts achieving ASDAS40 and AS Disease Activity Score (ASDAS)-c2.1 (low disease activity) were higher in BKZ-randomised TNFi-naïve/IR pts vs PBO. In both TNFi-naïve/IR continuous BKZ-treated pts, responses were similar and increased to Wk 52 (Figure 1). Similar substantial reductions from baseline in ASDAS-CRP and MRI inflammation by Wk 16 were also achieved with BKZ vs PBO in both TNFi-naïve and IR pts; in continuous BKZ-treated pts this was sustained or further improved through week 52. Comparable improvements in functional pain, nocturnal spinal pain and ASQoL were observed through 52 wks with BKZ in TNFi-naïve/IR pts (Table 1).

Conclusion: Across the full axSpA disease spectrum, BKZ treatment resulted in clinically relevant improvements in key efficacy outcomes vs PBO, including suppression of inflammation and improvements in physical function and QoL, regardless of prior TNFi exposure. The improvements with BKZ at Wk 16 were sustained to Wk 52.

**POS108**

**EFFICACY OF UPADACITINIB IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN EARLY VersUS ESTABLISHED DISEASE**

**Authors:** Y. Navarro-Compán1, F. Van den Bosch2, P. D. Sampaio-Barros2, F. Ganz2, A. Billant1, Y. Duan3, K. D'Silva4, P. Wung4, A. Ostof5, S. Ramiro1, 1Hospital Universitario La Paz, Departamento de Rheumatology, Madrid, Spain; 2Ghent University Hospital, Department of Internal Medicine and Pediatrics, Gent, Belgium; 3Hospital das Clinicas da Universidade de Sao Paulo, Division of Rheumatology, Sao Paulo, Brazil; 4AbbVie, Global Development, Baar, Switzerland; 5AbbVie, Department of Immunology, North Chicago, United States of America; 6Cabrin Hospital, Monash University & Emeritus Research, Melbourne, Australia; 7Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands.

**Background:** The phase 3 SELECT-Axis 2 trial (NCT04169973) assessed the efficacy and safety of upadacitinib (UPA) in patients with non-radiographic axial spondyloarthritis (nr-axSpA). This subgroup analysis investigated the efficacy of UPA in early versus established disease.

**Objectives:** This post hoc analysis evaluated the rates of achievement of ≥40% improvement in ASAS score (ASAS40 response) and Ankylosing Spondylitis Disease Activity Score (ASDAS) low disease activity (LDA; <2.1) at week 14 in early versus established disease (defined as symptom duration <2 versus ≥2 years).

**Methods:** In SELECT-Axis 2[1], adult patients with or without prior biologic DMARD (bDMARD) exposure, with a clinical diagnosis of axSpA, fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for nr-axSpA, and with objective signs of active inflammation on at least 1 of 8 sites (joints and/or high-sensitivity (hs)-CRP exceeding the upper limit of normal (2.87 mg/L) at screening, were randomized 1:1 to UPA 15 mg once or daily placebo (PBO) for 52 weeks. Response rate, relative risk (RR; UPA versus PBO), and RR ratio (RR; early versus established disease) are reported. When interpreting RRRs, a 95% confidence interval (CI) that crosses 1 indicates no statistically significant difference between the groups being compared.

**Results:** Baseline characteristics were similar in patients with early versus established disease, although the proportion of females, mean age, and rates of prior bDMARD exposure were higher in established versus early disease (Table 1). Mean symptom duration was 1.0 versus 10.9 years in patients with early versus established disease. ASAS40 and ASDAS LDA response rates at week 14 were significantly increased with UPA versus PBO in both early and established disease (ASAS40: 61.3% versus 16.0% and 40.3% versus 24.0%; ASDAS LDA: 64.5% versus 16.0% and 37.1% versus 18.9%; respectively) (Figure 1). For ASAS40 and ASDAS LDA, the RR of response for UPA versus PBO was greater in early versus established disease (3.9 versus 1.7 and 4.4 versus 1.9, respectively). RRRs for ASAS40 and ASDAS LDA for early versus established disease were 2.3 (95% CI: 0.77, 6.95) and 2.3 (95% CI: 0.75, 6.81), respectively, reflecting no statistically significant difference in treatment response between early and established disease.

**Conclusion:** UPA 15 mg is more efficacious than PBO in reducing signs and symptoms of nr-axSpA, regardless of symptom duration. Although treatment responses were numerically higher in early disease, the differences versus established disease were not statistically significant.

a clinical indicators to support characterisation of the axial PsA phenotype within large clinical datasets and identify clusters with potential therapeutic or prognostic significance in PsA patients (pts) with axial manifestations.[1]

Objectives: To identify pt clusters based on baseline (BL) demographics and clinical indicators to support characterisation of the axial PsA phenotype within the spondyloarthritis (SpA) spectrum.

Methods: Pooled BL demographics and clinical data of secukinumab (SEC)-treated pts from 10 Phase-3 studies: FUTURE 1–5 (PsA), MEASURE 1–4 (ankylosing spondylitis, AS) and MAXIMISE (PsA with axial manifestations) were treated pts from 10 Phase-3 studies: FUTURE 1–5 (PsA), MEASURE 1–4 (ankylosing spondylitis, AS) and MAXIMISE (PsA with axial manifestations) were explored across the identified clusters and clinical indicators.

Results: Eight distinct clusters were identified (n=3907, Figure 1 and Table 1). Pts with PsA with axial manifestations (MAXIMISE) were overrepresented in clusters 6–8. In pts cluster 6 (mean age 48 yrs; 64% male) were overweight with lower polyarticular joint counts (mean 11 joints) and tenderness focused on the feet, wrists and hands. Pts in cluster 8 were mostly pts with AS (mean age 43 yrs; 64% male), less overweight and oligoarthritis and high prevalence of spinal pain. Pts with PsA (FUTURE) were overrepresented in clusters 1–5. Longitudinal analysis showed significant improvements with SEC 300 mg vs 150 mg in clusters 6 and 8 for TJC, and cluster 7 for SJC.

Conclusion: PsA clusters obtained by ML in the pooled dataset indicate phenotypic heterogeneity of pts with PsA with axial manifestations and overlapping features across the SpA spectrum.

Objectives: To identify biological pathways modulated by UPA in nr-axSpA and bDMARD-IR AS patients based on an extensive proteomic profiling, emphasizing those associated with disease activity at baseline.

Methods: A subgroup of patients from the SELECT-Axis 2 program, with available biomarker samples, were selected for analysis (nr-axSpA PBO: n = 82; nr-axSpA UPA: n = 82; bDMARD-IR AS PBO: n = 111; bDMARD-IR AS UPA: n = 112). In addition, samples from 24 age- and gender-matched healthy volunteers (HVs) were included in the analysis. The levels of 1463 unique protein biomarkers (pBMs) were analyzed using proximity extension assay technology. Differences in pBMs levels between patients and HVs and their changes from baseline upon treatment were expressed as Log2 Fold Changes (Log2 FC). Relationships between pBMs levels and the Ankylosing Spondylitis Disease Activity Score using C-reactive protein (ASDAS-CRP) were derived using Pearson’s correlation. A repeated measure mixed linear model identified pBMs differentially modulated by UPA. All tests were corrected for multiple testing using the Benjamini-Hochberg method. Significance threshold was defined as FDR ≤ 0.05. We used a commercially available software application for pathway analysis.

Results: At baseline, we identified 174 (nr-axSpA) and 178 (bDMARD-IR AS) pBMs that were significantly differently expressed in patients compared to HVs. Only 24 out of 1463 pBMs tested were differently expressed between the two patient populations. Notably, interleukin-6, matrix metalloproteinase-1, metalloproteinase-3, and interleukin 17 receptor A were significantly more elevated in bDMARD-IR AS patients than in nr-axSpA patients. The pathway enrichment analysis on the differential pBMs pointed to a dysregulation of the adaptive and innate immune systems, increase in endothelial activation, and damage to connective tissue in both patient groups, although more pronounced in bDMARD-IR AS patients. Baseline levels of 49 (4 negatives and 45 positives) pBMs correlated with baseline ASDAS-CRP in the nr-axSpA and bDMARD-IR AS patients, respectively. Treatment with UPA resulted in a broad modulation of pBMs at weeks 2 and 14 in both patient groups, with a larger effect in bDMARD-IR AS patients than in nr-axSpA patients. Based on pathway prediction analysis, the effects of UPA on pBMs were consistent with the inhibition of the adaptive (T cell activation and migration, and antigen presenting cell activation) and innate (phagocyte and granulocyte migration and activation) immune pathways. The effects of UPA treatment on pBM correlating with ASDAS-CRP at baseline were consistent with UPA’s broad activity on potential pathogenic pathways in both nr-axSpA and bDMARD-IR AS patients (Figure 1).

Conclusion: While presenting different degrees of axial skeletal involvement, nr-axSpA and bDMARD-IR AS patients share common pathogenic pathways, with a more pronounced dysregulation observed in the latter group as observed from our data. Treatment with UPA inhibited multiple potentially pathogenic pathways associated with disease activity at baseline in nr-axSpA and bDMARD-IR AS patients. These observations are consistent with prior analyses in bDMARD-naïve AS patients[3]. We propose that the clinical efficacy of UPA in these 2 patient populations may result, at least in part, from its broad biological activity observed at the protein level.

Background: Combined biological or targeted therapy (CBTT) is rarely considered in clinical practice due to not being recommended in clinical guidelines, potential safety concerns and high costs. Successful experiences have been found with CBTT in refractory patients with inflammatory bowel disease (IBD). Previous early data in selected refractory spondyloarthritis (SpA) have shown encouraging results1.

Objectives: Our aim was to assess real-world effectiveness and safety of CBTT in a wider SpA population.

Methods: This is a retrospective multicenter study. We identified patients with SpA and simultaneous combined use of two biological or targeted (excluding apheresis) agents with different therapeutic targets since 2017. All patients fulfilled axial or peripheral SpA ASAS criteria and signed written informed consent. Demographic, clinical, laboratory, and safety data were collected from electronic medical records. Cut-offs for remission/low activity criteria for axial/peripheral disease were ASDAS-CRP <1.3 <2.1 or DAS28-CRP <2.6 <3.2 or DAPSA <4 <14 respectively. Major clinical improvement (MCI) was defined as a change in ASDAS-CRP of 2 and DAS28-CRP >1.2 units and improvement of >85% in DAPSA.

Results: A total of 39 CBTT courses were identified in 35 SpA patients (Table 1). The main indication for CBTT was active musculoskeletal disease (Table 2). Three patients presented remission or low SpA activity at baseline and were excluded in the efficacy SpA analysis. Most patients (89.7%) who had previously failed at least one of the two therapies used in CBTT. The most common combination was TNF inhibitor plus IL12/23 inhibitor agent (n=20; 51.2%). Median exposure to CBTT was 16 months (IQR 11-24). At last follow-up, we observed a significant mean reduction in ASDAS-CRP (2.07; 95% CI: 1.31-2.83; p=0.001). Remission/low activity rates were 52.7%, and 61.1% (n=22) reached MCI. In a bivariate analysis, patients who reached MCI had a lower baseline ASDAS-CRP than those who did not (4.9 vs 6.2, p=0.032). Nine patients discontinued due to inefficacy, seven of them because of IBD activity. In 39 CBTT courses, 4 serious AE were identified in only 3 patients: non-infectious pulmonary infiltrates, a staphylococcal bacteremia and a patient with cytomegalovirus colitis and esophageal candidiasis.

Conclusion: Our preliminary results suggest that CBTT might be a feasible alternative in selected refractory multidomain SpA patients, with acceptable effectiveness/safety ratio. Prospective wider studies are warranted to confirm these data.
were analyzed in peripheral blood samples from 40 axSpA patients before and during treatment. While several studies have provided mechanistic insights into TNFi action, much less is known how IL-17i affect immune responses in patients.

**Objectives:** To compare the mechanisms of action of these two drugs in axSpA patients in vivo.

**Background:** IL-17A-blockade had very limited effects on systemic immune responses after IL-17i or TNFi treatment, using highly standardized whole-blood stimulation assays. Changes in gene expression were determined by RNA sequencing and secreted molecules were measured using proximity ligation assays. Pathways analysis revealed major effects of TNFi on the expression of genes involved in protection from bacterial (Tuberculosis, Legionellosis), viral (EBV, Influenza) and parasitic (Leishmaniasis, Toxoplasmosis) infections (Figure 1). Analysis of secreted inflammatory cytokines and chemokines showed that TNF-blockade also strongly affected innate and adaptive immune cell signaling, while only minor changes were observed in stimulation cultures from IL-17i-treated axSpA patients. Furthermore, we noted major effects of TNFi, but not of IL-17i, on neutrophil and monocyte counts in the circulation of treated patients.

**Conclusion:** We show that the two currently used biotherapies of axSpA act by strikingly distinct cellular and molecular mechanisms. While anti-TNF therapy has major effects on systemic immune responses with potential implications for increased susceptibility to infectious microorganisms, IL-17 inhibitors had a lesser impact on systemic immune responses compared to TNFi, suggesting that they may rather act on non-immune cells and/or in inflamed tissues.

**Background:** IL-17A inhibitors (IL-17i) and TNF-inhibitors (TNFi) are currently the only biologic drugs available as first line treatment in axial spondyloarthritis (axSpA). While several studies have provided mechanistic insights into TNFi action, much less is known how IL-17i affect immune responses in patients.

**Objectives:** We have compared the effects of IL-17i and TNFi on immune cell frequencies and induced immune responses to obtain information about the mechanisms of action of these two drugs in axSpA patients in vivo.

**Methods:** Induced immune responses to microbial and pathway-specific stimuli were analyzed in peripheral blood samples from 40 axSpA patients before and during treatment. We have compared the effects of IL-17i and TNFi on immune cell frequencies and induced immune responses to obtain information about the mechanisms of action of these two drugs in axSpA patients in vivo.

**Conclusion:** We have compared the effects of IL-17i and TNFi on immune cell frequencies and induced immune responses to obtain information about the mechanisms of action of these two drugs in axSpA patients in vivo.

**CHARACTERISTICS OF DIFFICULT TO TREAT AXIAL SPONDYLOARTHRITIS: A COMPARATIVE ANALYSIS**

**Keywords:** Spondyloarthritis, Real-world evidence, Disease-modifying drug (DMARDs)
Background: The concept of difficult-to-treat rheumatoid arthritis (D2T RA) has recently emerged. It is defined by the persistence of disease activity and the failure of at least 2 bDMARDs of different mechanisms of action (MoA) [1]. In this definition, the period during which the treatments have failed is not included. The D2T concept has not yet been applied with consensus in axial spondyloarthritis (axSpA).

Objectives: To study the characteristics of patients with D2T axSpA to better identify the potential causes of treatment failure. The second objective was to identify the potential causes of treatment failure. The second objective was to identify the potential causes of treatment failure.

Methods: A multicentric retrospective longitudinal study was performed in secondary and tertiary centers. axSpA diagnosis was based on ASAS criteria. Patients were followed up from January 2016 to December 2021. Patients starting with at least 2 b/tsDMARDs with a minimum of 2-year follow-up were included. D2T axSpA patients were defined as patients who received more than 2 b/tsDMARDs with different MoA among b/tsDMARD available. These patients were compared to non-difficult-to-treat axSpA patients (nD2T axSpA) using statistical tests. Very D2T axSpA patients were defined as patients who received at least 2 b/tsDMARDs in less than 2 years during the time of follow-up.

Results: 311 patients were included, 88 were D2T axSpA and 223 nD2T axSpA. Baseline characteristics are presented in the Table 1. No statistical difference was found between the 2 groups regarding main comorbidities, including fibromyalgia and depression. Among the D2T patients, 76 (66%) had presented a primary or secondary inefficacy from 2 drugs with different MoA and 12 (14%) presented a concomitance to TNF inhibitor or IL17 inhibitor (multiple sclerosis, inflammatory bowel diseases, recurrent uveitis, solid cancer less than 5 years old). Seven patients were categorized as very D2T axSpA. When compared to the rest of the D2T axSpA group, no significant difference was observed.

Conclusion: Significant differences were found between the characteristics of patients D2T axSpA and nD2T axSpA, which were the smoking status, axSpA duration, presence of arthritis, history of uveitis and baseline BASDAI. Limitations exist about applying the EULAR D2T RA definition to axSpA. The inclusion of a time frame should also be considered.

Poddubnyy9, 10, Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 2Bochum Ruhr-Universität, Rheumatology, Bochum, Germany; 3Leiden University Medical Center; Department of Rheumatology, Leiden, Netherlands; 4University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom; 5Charité - Universitätsmedizin Berlin and German Rheumatism Research Centre, Rheumatology, Berlin, Germany

Background: SURPASS, a phase IIb randomised controlled study in patients (pts) with radiographic axial spondyloarthritis (r-axSpA), found low spinal radiographs (progression over 2 years with no significant difference between the secukinumab (SEC) and adalimumab biosimilar (SDZ-ADL) arms,[1,2] Basel (BSSL) radiographic damage (presence of syndesmophytes) and elevated C-reactive protein (CRP) levels have been identified as predictors of radiographic progression in r-axSpA.[3]

Objectives: To evaluate the effect of SEC and SDZ-ADL on spinal radiographic progression in subgroups of pts based on the presence of syndesmophytes and elevated high-sensitivity CRP (hsCRP) levels at BSSL, from the SURPASS study.

Methods: Biologic-naive pts with active r-axSpA and with hsCRP ≥5 mg/L and/or ≥1 syndesmophyte(s) on spinal radiographs were randomised (1:1:1) to SEC (150 or 300 mg; dose-blinded) or SDZ-ADL (40 mg; open label). Pts were categorised into the following subgroups at BSSL: hsCRP <5 mg/L (CRP−), presence of syndesmophyte(s) (Synd+), absence of syndesmophyte(s) (Synd−), and CRP+Synd+. The proportion of pts with no radiographic progression (change from baseline in modified Stoke Ankylosing Spondylitis Spinal Score [mSASSS] ≤0.5), mean change from BSSL in mSASSS, and proportion of pts with no new syndesmophytes(s) in each subgroup at week 104 (all as observed were reported).

Results: Of the 859 pts, 653 (76%) were CRP+, 627 (73%) were Synd+, and 466 (54%) were CRP+Synd+. Expectedly, pts from subgroups without predictive factors (especially Synd−, followed by CRP−) had lower rates of radiographic progression compared to SEC and SDZ-ADL arms regardless of the presence or absence of specific predictive factors for progression (syndesmophytes/elevated CRP). The Synd− subgroup followed by the CRP− subgroup showed the least radiographic progression in all radiographic outcomes (as indicated by the higher proportion of pts with no radiographic progression and no new syndesmophytes, and lower mean change from BSSL in mSASSS), across treatment arms (Figure 1). The CRP+Synd+ subgroup followed by the Synd+ subgroup and the CRP+ subgroup had higher radiographic progression compared with the Synd− and CRP− subgroups (Figure 1).

Conclusion: Spinal radiographic progression over 2 years was low with no notable difference between SEC and SDZ-ADL arms regardless of the presence or absence of specific predictive factors for progression (syndesmophytes/elevated CRP). Expectedly, pts from subgroups without predictive factors, especially Synd−, followed by CRP− had lower rates of radiographic progression.

V. Navarro-Compán1, A. Deodhar2, R. Bahiri3, A. G. Bushmakin4, J. C. Cappellini5, C. Kinch5, J. Rammougu5, La Paz University Hospital, IdiPaz, Department of Rheumatology, Madrid, Spain; 2Oregon Health & Science University, Division of Arthritis and Rheumatic Disease, Portland, OR, United States of America; 3El Ayachi Hospital Medical University, Department of Rheumatology, Rabat, Rabat-Salé-Kénitra, Morocco; 4Pfizer Inc, Statistical Research and Data Science Center, Groton, CT, United States of America; 5Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada; 6Pfizer Inc, Innovative Medicines/Emerging, Casablanca, Morocco

Background: Pain, morning stiffness and disease activity are core domains of ankylosing spondylitis (AS), relevant to patients (pts) and physicians. AS treatment guidelines recommend using the AS Disease Activity Score C-reactive protein (ASDAS,CRP) to assess disease activity. Greater improvements in pain, morning stiffness and disease activity were previously shown with tofacitinib vs placebo (PBO) in pts with AS.[1] There are limited data on time to improvement in these core domains in pts with AS receiving tofacitinib.

Objectives: To estimate the median time to improvement of pain, morning stiffness and disease activity in tofacitinib-treated pts with AS.

Methods: This post hoc analysis used data from a Phase 3 trial (NCT03502616)[1] in pts with AS receiving tofacitinib 5 mg twice daily (BID) or PBO to Week (W)16. After W16, all pts received open-label tofacitinib 5 mg Bid to W48. Outcomes included nocturnal pain (numerical rating scale 0–10), morning stiffness (mean of Bath AS Disease Activity Index [BASDAI] Questions 5 and 6), BASDAI total score and ASDAS,CRP. Median time (weeks) to initial improvement events was estimated using non-parametric Kaplan-Meier models. Initial improvement event was defined as time to first post-baseline observation with an improvement of ≥30% (nocturnal pain ["much improved"]23, ≥50% (nocturnal pain ["very much improved"]22, ≥30% improvement in morning stiffness and BASDAI total score for tofacitinib was 12 weeks, and 32 weeks (16 weeks since switch to tofacitinib) for both thresholds.

Results: Overall, 269 pts (tofacitinib: n=133; PBO—tofacitinib: n=136) were assessed. Median times to initial improvement events were shorter with tofacitinib vs PBO—tofacitinib (p<0.05 [Table 1]). Median times to initial ≥30% and ≥50% improvement in nocturnal pain for tofacitinib were 4 and 8 weeks, respectively, and 24 weeks (8 weeks since switch to tofacitinib) for both thresholds for PBO—tofacitinib. Median time to initial ≥50% improvement in morning stiffness and BASDAI total score for tofacitinib was 12 weeks, and 32 weeks (16 weeks since switch to tofacitinib) for PBO—tofacitinib. Median time to ASDAS,CRP improvement ≥1.1 for tofacitinib was 4 weeks, and 24 weeks for PBO—tofacitinib (not estimable [NE] for ASDAS,CRP improvement ≥2.0 [both treatment arms]). Limitations: this was a post hoc analysis, there was no active treatment comparator, trial pt population may not reflect routine care pt population and comparisons with PBO were only possible to W16.
**Background:** Janus kinase inhibitors (JAKis) are a group of disease-modifying antirheumatic drugs (DMARDs) used for the treatment of several immune-mediated inflammatory arthritides (IMAs) including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA). There are several JAK inhibitors (JAKis) with different selectivity already approved or in clinical and preclinical evaluation[1]. Thus, tofacitinib is a JAK1/3 inhibitor, baricitinib is a JAK2/3 inhibitor, filgotinib and upadacitinib are selective JAK1 inhibitors, decernotinib is a selective JAK1 inhibitor[2] and deucravacitinib is a selective tyrosine kinase 2 (TYK2) inhibitor[3]. The downstream effects on cytokine expression profile of JAKis with different selectivity is not fully understood.

**Objectives:** Here we investigate whether JAKis with different selectivity show differences in downstream cytokine expression in an in vitro model of immune-mediated inflammatory arthritis.

**Methods:** Synovial fluid mononuclear cells (SFMCs) from patients with peripheral SpA (n=3), PsA (n=3), juvenile idiopathic arthritis (n=4), and unspecified inflammatory arthritis (n=1) were cultivated for 48 hours with the JAKis prior to listing. Culture medium and DMSO were used as negative controls. In vitro drug response was assessed by Mesoscale V-PLEX Proinflammatory Panel 1 Human Kit measuring interferon-γ (IFN-γ), interleukin 1 (IL-1), IL-2, IL-6, IL-10, IL-12/70, IL-13 and TNF-α.

**Results:** First, we tested whether JAKis with a similar selectivity had comparable effects on the secretion of cytokines. Indeed, JAKis with selectivity towards JAK1 and JAK3 clustered together in the hierarchical analysis. Then, we examined whether there was a difference between the six JAKis on an individual level. All JAKis with a JAK1 selectivity decreased the cytokine secretion more than the JAK3/2 inhibitor baricitinib (filgotinib vs. baricitinib, p<0.005; upadacitinib vs. baricitinib, p<0.05; tofacitinib vs. baricitinib, p<0.05). There was no difference between the JAKis with JAK1 selectivity and decernotinib (JAK3) or deucravacitinib (TYK2).

**Conclusion:** Similarities in mode of action for the six JAKis were reflected in drug response measured by multiple cytokine secretions. Generally, JAKis with JAK1 and JAK3 selectivity decreased total cytokine secretion the most. In selected patients, specific JAKis decreased total cytokine secretion considerably more than the remaining JAKis, while most patients had an equal response to all JAKis.

**Background:** The Assessment of SpondyloArthritis international Society Health Index (ASAS HI) is a validated health outcome measure used to assess functioning and health in patients (pts) with axial spondyloarthritis (axSpA)[1]. Two thresholds for clinical improvement have been recently proposed: improvement ≥3 points and a 30% improvement from baseline [1,2]. However, an exploration of the optimal threshold in an independent cohort has not been carried out to date.

**Objectives:** Using data from the COAST trials, this analysis aimed to test the discriminatory capacity of the ASAS HI at different thresholds of improvement.

**Methods:** This post hoc analysis included patients treated with ixekizumab (IXE) 80 mg every 4 weeks (Q4W) or placebo (PBO) from the intent-to-treat populations of COAST-V (NCT02696785) and COAST-W (NCT02696798) for radiographic (r)-axSpA, and COAST-X (NCT02757352) for non-radiographic (nr)-axSpA over 16 weeks. To assess the discriminatory capacity of the ASAS HI, response rates at Week 16 were compared between IXE Q4W and PBO using Fisher’s exact test. P-values (coefficients ranging from -1 to +1) were calculated to compare the degree of association between the level of improvement and treatment allocation. Missing data were handled using non-responder imputation.

**Results:** ASAS HI data at Week 16 were available for pts with r-axSpA from COAST-V (IXE Q4W, N=81; PBO, N=87) and COAST-W (IXE Q4W, N=114; PBO, N=104) and pts with nr-axSpA from COAST-X (IXE Q4W, N=98; PBO, N=105). Percentages of pts reaching improvement scores for different study arms are shown in Figure 1. Differences in response rates by the various absolute or

relative thresholds for improvement are shown in Table 1. Data demonstrated
an inconsistent picture of the best performing threshold between the different
COAST studies. While for COAST-V discriminatory capacity were demonstrated
for higher values this was opposite to COAST-W, and there was no clear discriminating threshold in COAST-X (Table 1, Figure 1). The majority of Phi coefficients
were below 0.2, suggestive of low discriminatory capacity.
Conclusion: In this post hoc analysis of pts from the COAST trials at Week 16,
several thresholds of improvement of the ASAS HI seem to have discriminating
capacity. However, there were some differences between the COAST trials and
no single threshold worked best in the r-axSpA (bDMARD-naïve and experienced) and nr-axSpA populations.

POS1119

ARE WE TREATING-TO-TARGET IN
SPONDYLOARTHRITIS (SPA)? A ONE-YEAR ANALYSIS
FROM THE ASIA PACIFIC LEAGUE OF ASSOCIATIONS
FOR RHEUMATOLOGY (APLAR) SPA REGISTRY

Keywords: Spondyloarthritis

Background: Data on the extent to which internationally agreed treat-to-target
(T2T) recommendations were applied in clinical practice in patients with spondyloarthritis (SpA) across the Asia-Pacific region is lacking. The APLAR SpA Registry is a multi-centre study aiming to assess the utility of early diagnosis and
intensive protocolized treatment to patients with SpA on the long-term outcome.
Objectives: This analysis aimed to evaluate the extent of T2T achievement after
1-year intensive treatment in patients with SpA.
Methods: Patients who fulfilled the CASPAR 2006 classification criteria for psoriatic arthritis (PsA), and 2009 ASAS classification for axial spondylitis (AxSpA)
were recruited. The current analysis included the first 99 patients reaching the
1-year timepoint across 6 Asia-Pacific regions.
Results: 49 patients with PsA (age: 52±11 years, 27(55%) male, disease duration: 6.0±7.9 years) and 50 patients with AxSpA (age: 40±14 years, 36(72%)
male, disease duration: 5.9±7.6 years) were included. All of them were Asian.
After 1-year treatment, there were significant improvements in disease activity (Disease Activity in Psoriatic Arthritis (DAPSA): 15.3±11.6 at baseline vs
10.1±11.2 at 1-year, p=0.002; Ankylosing Spondylitis Disease Activity Score
(ASDAS): 2.4±1.0 at baseline vs 1.9±0.9 at 1-year, p=0.003). Other characteristics are shown in Table 1. Concerning medication use, there was an increase in
the number of PsA patients receiving conventional synthetic disease-modifying
drugs (csDMARDS, 65% at baseline to 72% at 1-year) and biologic DMARDS
(bDMARDS, 24% at baseline to 43% at 1-year). For AxSpA, the prevalence of
csDMARDs use decreased (30% at baseline to 18% at 1-year) while the prevalence of bDMARDs use increased (32% at baseline and 54% at 1-year). Patients
in both groups required less NSAIDs (Figure 1). Regarding T2T, 63% and 51%
of PsA patient achieved DAPSA-low disease activity (DAPSA-LDA) and minimal disease activity (MDA) respectively, while 66% of patients with Axial SpA
achieved ASDAS-LDA. The MDA and ASDAS-LDA achievement rate was slightly
higher than that of the tight control arm of TICOPA (41%)[1] and TICOSPA cohort
(60%)[2] respectively. The bDMARDs use in TICOPA cohort was 37% and that
in TICOSPA was 57%, both comparable to our APLAR SpA cohort (Figure 1).
There was no significant difference in baseline demographics and clinical features between patients who could or could not achieve treatment target, except
a lower patients’ pain and global assessment, and lower functional disability in
patients who achieved DAPSA-LDA at 1-year.
Conclusion: Implementing the T2T strategy in a patient with SpA is feasible in
the selected sites of the APLAR SpA registry. We expect more long-term outcome data in the following years regarding other outcomes.

Background: While data on real-life SEC retention rate in patients (pts) with axSpA is accumulating, there are few data on predictive factors for this retention. Presence of objective sign of inflammation (OSI), especially increased baseline CRP level, is known to be predictive of efficacy of anti-TNFs and their retention in axSpA.

Objectives: To assess whether OSI, especially increased baseline CRP level, were predictive of SEC retention at 1 year in axSpA.

Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2018, b) with at least one dose of SEC between August 11th 2016 and August 31st 2018, c) having a one-year follow-up period. Retention rate of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following: CRP ≥5 mg/l or ESR ≥28 mm/h if CRP not available (CRP+) within the 3 months before initiation of SEC and MRI inflammation at the sacroiliac or spine level (MRI+) at any time. The a priori selected potential predictive factors of the SECU 1 year retention (CRP+, MRI+, age, sex, BMI, smoking, HLA B27, non-radiographic vs radiographic axSpA, past or present uveitis/Inflammatory Bowel Disease/psoriasis/arthrisis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SEC maintenance dose, concomitant csDMARD/oral corticosteroids/proton pump inhibitor at SEC initiation, history of depression/ fibromyalgia) were analyzed by cox model regression. Only variables with <20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables =20%; significance level for removing variables =10%), except for CRP and MRI which were forced into the model whatever their significance level or rate of missing data.

Results: In total, 906 pts from 47 centers (male: 42.2%; mean age: 46.2 ± 11.7 years, mean disease duration: 9.3 ± 9.1 years) were included in the analysis. The mean baseline CRP (± SD) was 11.1 ± 17.5 mg/L. At initiation of SEC, 86.3% of pts had ≥1 OSI (413.3%, CRP+, and 69.4% MRI+) and respectively 8.0%, 14.9% and 77.1% were in 1st, 2nd and ≥ 3rd line (L) of biologic/targeted synthetic DMARD. The 1-year retention rate for SEC was 59% [95% CI: 55%-62%]. This retention at one year was 62.4% vs 59.1% and 57.4% vs 66% in patients with CRP+ vs CRP- and MRI+ vs MRI- respectively. In univariate cox regression, CRP+ was not predictive of SEC discontinuation at 1 year (HR = 0.90 [0.71-1.16], p=0.422) nor was MRI+ (HR=1.29 [0.99-1.68], p=0.063). In multivariate cox analysis, after adjustment, these results were confirmed for CRP+ but MRI+ was identified as predictive of a worst SEC retention at 1 year (Table 1). In multivariate analysis lack of prior exposure to anti-TNF inhibitors, absence of IBD and absence of history of depression were also associated with a better SEC retention at 1 year (at 10%).

Conclusion: The overall retention of SEC at 1 year in daily practice in France was 59% for axSpA patients with OSI level at SEC initiation, independently of CRP level at SEC initiation.

DOI: 10.1136/annrheumdis-2023-eular.2803
Background: Upadacitinib (UPA), a Janus kinase inhibitor, has demonstrated efficacy and an acceptable safety profile in patients (pts) with ankylosing spondylitis (AS) in the phase 3 SELECT-AXIS 1 and 2 program, including pts with an inadequate response or intolerance to biologic disease-modifying antirheumatic drugs (bDMARD-IR) [1,2].

Objectives: To assess the 1-year efficacy and safety of UPA 15 mg once daily (QD) in bDMARD-IR pts with active AS. Similar efficacy was observed at wk 52 in pts who switched from PBO to UPA and continuous UPA groups, respectively. Safety was assessed through the cut-off date of May 19, 2022 in all pts who received ≥1 dose of UPA. Treatment-emergent adverse events (TEAEs) and TEAEs of special interest are presented as exposure-adjusted event rates (events/100 PY, respectively).

Methods: The design of the SELECT-AXIS 2 AS bDMARD-IR study has been described previously.[1] Pts who completed the 14-wk placebo (PBO)-controlled period were eligible to enter an ongoing long-term extension and receive open-label UPA 15 mg QD for up to 90 wks. This analysis evaluated efficacy over 52 wks in pts who received continuous UPA, and those who switched from PBO to UPA at wk 14. Efficacy endpoints included proportion of pts achieving Assessment of SpondyloArthritis international Society 40 response (ASAS40), ASAS partial remission (PR), ASAS (AS Disease Activity Score with C-reactive protein [CRP]) low disease activity (LDA; <2.1), ASAS inactive disease (ID; <1.3), and changes from baseline in ASAS and high-sensitivity CRP (hsCRP). As-observed (AO) and non-responder imputation with multiple imputation (NRI-MI) analyses are presented for binary endpoints and mixed model for repeated measures (MMRM) analyses for continuous endpoints. Safety was assessed through the cut-off date of May 19, 2022 in all pts who received ≥1 dose of UPA. Treatment-emergent adverse events (TEAEs) and TEAEs of special interest are presented as exposure-adjusted event rates (events/100 PY, respectively).

Results: A total of 420 pts were randomized and received study drug (PBO to UPA: n=209; continuous UPA: n=211). Response rates were maintained from wk 14 to wk 52 in the continuous UPA group, and responses were similar in the PBO to UPA group at wk 52. NRI-MI response rates at wk 52 for the PBO to UPA and continuous UPA groups, respectively, were: ASAS40 (64.6% and 65.9%), ASAS PR (92.2% and 93.3%), ASAS LDA (55.3% and 56.9%), and ASAS ID (25.2% and 26.0%) (Figure 1). Changes from baseline in ASAS and hsCRP were also similar between groups (-1.9 and -2.0, and -10.6 and -10.0 for the PBO to UPA and continuous UPA groups, respectively). Safety was assessed in 414 pts (334.4 PY of exposure) who received ≥1 dose of UPA (Table 1). Rates of serious TEAEs and TEAEs leading to study drug discontinuation were 9.9 and 3.0 E/100 PY, respectively. Rates of malignancy, major adverse cardiovascular events, and venous thromboembolic events were low (0.2, 0.2, and 0.4 E/100 PY, respectively).

Conclusion: UPA 15 mg demonstrated sustained efficacy up to wk 52 in bDMARD-IR pts with active AS. Similar efficacy was observed at wk 52 in pts with continuous UPA exposure and those who switched from PBO to UPA. UPA 15 mg was generally well tolerated in this bDMARD-IR population, with new safety signals identified.

Keywords: Prognostic factors, Spondyloarthritides, Real-world evidence
Background: The characteristics of patients receiving a new therapy might differ overtime since its launch (date of its availability in a specific region/country); the differences in these characteristics might impact the efficiency of this treatment.

Objectives: To compare the one year retention rate of SECU in axSpA and its predisposing factors with regard to its time of initiation (e.g. right after its launch or later).

Methods: Study design: Retrospective multicenter French study of axSpA patients a) having initiated and received at least one dose of SECU b) with at least a one year follow-up. Study periods: Two cohorts were evaluated with regard to the time of initiation of SECU: Cohort (C1): between August 11th, 2016 (time of the launch of SECU in France) and Aug 3rd 2018; Cohort 2 (C2): between sept 1st 2018 and Nov 13, 2020 (remotely from the launch).

Statistical analysis: The one year retention rate of SECU was estimated using the Kaplan Meier technic and Cox models and was used to compare the retention rate performed in C1 and C2. Preselected factors of SECU retention at 1 year (≥1 Objective Sign of Inflammation [CRP> N, MRI-inflammation at the sacroiliac or spine level], age, sex, BMI, smoking, HLA B27, non-radiographic vs radiographic axSpA, past or present uveitis/ Inflammatory Bowel Disease (IBD)/ psoriasis/ arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SECU maintenance dose, concomitant csDMARD/ oral corticosteroids/ proton pomp inhibitor at SECU initiation, history of depression/ fibromyalgia) were analyzed by univariate and multivariate cox model regression. Only variables with <20% missing data were included in the model after multiple imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%).

Results: In total, 906 pts in C1 and 758 pts in C2 from 50 centers were included in the analysis. Pts characteristics (male: 42.8%, mean age: 46.5 ± 11.9 years, mean disease duration: 9.2± 9.4 years) were similar between the 2 cohorts. The 1 year retention rate was better in C2 vs C1 (64% [61-68%] vs 59% [55-62%], Hazard Ratio (HR)=0.84 [0.72-0.98], p = 0.03). Between C1 and C2, the proportion of patients receiving SECU as the 1st or 2nd line of biologic therapy increased from 23% to 40%. In the multivariate analysis, line of biologic therapy was the single predictive factor of the 1 year retention rate of SECU in both cohorts with a better retention rate for the 1st line of biologic therapy (Table 1).

Conclusion: These data showing a better retention rate at 1 year remotely from the launch of SECU, probably explained by its use at an earlier stage of the disease, suggest a change in the behavior of prescribing physicians probably reflecting a better confidence in this treatment. These data also underline the interest of iterative evaluations of treatments used in daily practice.

SLE, Sjön’s and APS - treatment

Keywords: Education, Systemic lupus erythematosus, Best practices

A. Cornet1, A. Sluijters2, F. Marchioni3, C. Hjelmested4, I. D. Povileva5, E. Koskin6, K. Blomkvist Sporre7, 1Lupus Europe, HQ, Brussels, Belgium; 2Lupus Europe, PAN, Brussels, Belgium

Background: Access to quality disease information is one of the cornerstones of therapeutic education and critical to help the doctor-patient dialogue and adherence to treatment. Lupus patients and doctors alike lack the time in consultation to address the many questions patients have. As a result, patients often rely on poor quality or unverified information from the web. For non-English speakers, the language barrier is adding yet another obstacle to quality therapeutic education.

Objectives: To provide access to doctor verified SLE quality information on-line, in the mother language of 95%+ of the European population so that doctors can refer patients to quality information sources.

Methods: With the endorsement of ERN ReCONNET reference network, Lupus Europe and doctors from ReCONNET’s SLE Working group have developed a multilingual Euro-wide website answering the top 100 questions patients have about lupus. The starting point to build the content has been the French book “lupus en 100 questions” authored by lupus experts from the French FA2IR. Working extensively with patients from Lupus Europe PAN, the list of questions has been adjusted, answers to existing questions have been checked and validated or adjusted for up-to-dateness. New patient questions have been answered by lupus specialists in collaboration with patients. The resulting documents have been translated in English and the translations validated by both patients and doctors. This core English version has then received feedback from ERN ReCONNET SLE WG doctors. Finally, the end result has been translated in more than 15 languages, verified by native lupus doctors and patients prior to being put on line. This exercise is continuing at the time of writing the abstract, with the goal of covering more than 20 languages and 99% of European population by end 2023. The web site is managed and controlled by Lupus Europe, the European Lupus patients organisation. Aside from this ‘one-shot’ effort, a process has been designed to collect questions and comments from patients and doctors. Those will then feed the on-going maintenance of the information. New developments or new questions will be used to systematically review the content and update it using a Delphi process within the ERN ReCONNET SLE Working group.

Results: lupus100.org website provides free of charge quality information on lupus for patients, relatives, doctors or students. Its multilingual character allows all people in Europe with access to verified information in their own language, with lay terms. This non-commercial tool is available for doctors of all countries to grow their patients education on lupus and hence build a stronger therapeutic alliance, minimising the time lost in fighting wrong information.

Conclusion: A new tool is available for doctors and patients to build lupus education. The challenges are now (a) to maximise its reach by ensuring all patients and doctors are aware of the initiative, and (b) to ensure that currency is maintained medium to long term.

HYDROXYCHLOROQUINE USE IN PREGNANT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOUS AND MAJOR CONGENITAL MALFORMATIONS IN THE OFFSPRING

Keywords: Registries, Pregnancy and reproduction, Systemic lupus erythematosus

N. V. Nguyen1, E. Svennungsson2, A. Dominiczak3, K. Helgren1, J. Simard4, E. Arkema1, Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; 2Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; 3Stanford School of Medicine, Division of Immunology and Rheumatology, Department of Medicine, California, United States of America

Background: Hydroxychloroquine (HCQ) is currently recommended for all pregnant women with systemic lupus erythematosus (SLE) if tolerated. Some studies have reported an increased risk of malformations associated with HCQ, but others find no increased risk.

Objectives: To assess the risk of major congenital malformations (MCM) associated with exposure to HCQ during the 1st trimester in the offspring of women with SLE.

Methods: We conducted a population-based cohort study of pregnancies with a singleton birth from 2006 to 2020 among women with prevalent SLE in Sweden. Pregnancies were identified from the Medical Birth Register (MBR). Prevalent SLE was defined as having at least two ICD-coded visits in the National Patient Register before pregnancy, with at least one with an SLE specialist. The exposure was defined as filing at least one HCQ prescription during the 1st trimester (Prescribed Drug Register). The unexposed births were required to not have any HCQ dispensations from three months preconception to the end of the 1st trimester. The outcome was any ICD code for MCM in the offspring assessed at birth listed in the MBR, defined according to the European Surveillance of Congenital Anomalies classification. Inverse probability of treatment weighting (IPTW) using propensity score for adjusted one HCQ during pregnancy was minimised using standardised mean difference (SMD) for baseline characteristics, comorbidities (e.g., diabetes, other autoimmune diseases), and medication use (e.g., corticosteroids, other disease-modifying anti-rheumatic drugs) in the propensity score model as a priori variables. Risk ratios and 95% confidence intervals (RR 95%CI) were estimated using modified Poisson regression models in the weighted population with robust variance estimation.

Results: The study population comprised 407 exposed births and 520 unexposed births. The mothers’ mean age at delivery was 32 (standard deviation ±3). Overall, there were 21 births with at least one MCM, corresponding to an overall risk of 2.3%. The most common type of MCM was ventricular septal defect (n = 6). The unadjusted risks of MCM among the exposed and unexposed were 2.7% and 13%, respectively (unadjusted RR 1.42, 95%CI 0.26-3.28). The IPTW-adjusted population achieved a balance across patient characteristics. The IPTW-adjusted RR was 1.59 (95%CI 0.63-7.15). The adjusted risk difference was 0.01 (95%CI -0.01-0.03). In a sensitivity analysis in which the exposure was defined as having at least one HCQ dispensation from three months preconception to the end of the 1st trimester, the IPTW-adjusted RR was 1.56 (95%CI 0.69-3.54). We could not examine different categories of HCQ daily dose due to very few events in each category.

Conclusion: In this birth cohort, our findings show an increased, but not statistically significant, risk of MCM at birth among women with SLE exposed to HCQ during the 1st trimester compared to those without HCQ exposure. Our findings should be interpreted considering the lack of data on early pregnancy termination or loss induced by MC. Future studies are warranted to investigate this association further and should utilize a longer follow-up for MCM ascertainment (i.e., within one year of birth). For managing SLE during pregnancy, the benefits of HCQ may still outweigh the risks.

THERAPEUTIC RANGE OF HYDROXYCHLOROQUINE BLOOD LEVELS CAN REDUCE ODDS OF HIGH LUPUS DISEASE ACTIVITY

Keywords: Treat to target, Systemic lupus erythematosus, Outcome measures

S. Gar1, B. Chewing2, S. Gomez3, C. Bartels4, 1University of Wisconsin, School of Medicine & Public Health, Medicine, Rheumatology, Madison, United States of America; 2University of Wisconsin, School of Pharmacy; Pharmacy, Madison, United States of America

Background: Hydroxychloroquine (HCQ) is the cornerstone of systemic lupus erythematosus (SLE or lupus) treatment, yet, the optimal dosing of HCQ in SLE is unknown. Reducing HCQ dose to 5mg/kg to limit toxicity, as suggested by the American Academy of Ophthalmologists (AAO),(1) also predicts increased flares. One study showed that only 34% of patients receiving AAO recommended HCQ dosing.(2) Therefore, establishing effective therapeutic ranges of HCQ blood levels may provide an opportunity to individualize HCQ dosing to maximize efficacy and limit toxicity.

Keywords: Treatment, Systemic lupus erythematosus, Outcome measures

S. Gar1, B. Chewing2, S. Gomez2, 1University of Wisconsin, School of Medicine & Public Health, Medicine, Rheumatology, Madison, United States of America; 2University of Wisconsin, School of Pharmacy; Pharmacy, Madison, United States of America

Background: Hydroxychloroquine (HCQ) is the cornerstone of systemic lupus erythematosus (SLE or lupus) treatment, yet, the optimal dosing of HCQ in SLE is unknown. Reducing HCQ dose to 5mg/kg to limit toxicity, as suggested by the American Academy of Ophthalmologists (AAO),(1) also predicts increased flares. One study showed that only 34% of patients receiving AAO recommended HCQ dosing.(2) Therefore, establishing effective therapeutic ranges of HCQ blood levels may provide an opportunity to individualize HCQ dosing to maximize efficacy and limit toxicity.
**Objectives:** The objective of this study was to examine the association of HCO blood levels with high lupus disease activity (HDA) in a prospective SLE cohort.

**Methods:** This cross-sectional study measured HCQ blood levels in unique SLE visits using liquid chromatography-tandem mass spectrometry. HCQ blood levels and SLE disease activity index (SLEDAI) scores were measured on the day of the visit for each patient. High lupus disease activity (HDA) was defined as SLEDAI scores ≥26.(3) To identify significant HCQ blood levels that determined lower odds of HDA, we examined associations between HDA and every 50-100 ng/ml increase in HCQ blood levels starting at 100 ng/ml through 1500 ng/ml. Other factors that can affect HCQ levels, such as patient-reported adherence, kidney function, and HCQ dose and timing, were included in multivariable models.

**Results:** Among 143 SLE patients in whom HCQ blood levels were measured, 92% were women and 32% were of non-White race or Hispanic ethnicity. HDA was noted in 16% of patients. We noted a 75% reduction in the odds of HDA at first HCQ blood levels of ≥750 ng/ml (Adjusted OR 0.25, 95% CIs 0.066-0.89, p-value = 0.035; Figure 1). This effect peaked with HCQ blood levels ≥1100 ng/ml with 93% lower odds of HDA at this level (Adjusted OR 0.07, 95% CIs 0.005-0.61, p-value = 0.038; Figure 1). Interestingly, levels of 1150 ng/ml or higher did not further reduce the odds of HDA (Figure 1).

Additionally, we noted that female sex was associated with 88% lower odds of HDA (Table 1), while other factors including HCQ dose or timing were not associated with HDA (Table 1).

**Conclusion:** We report an effective therapeutic range of HCQ blood levels, 750-1100 ng/ml, that significantly correlated with reduced risk of high lupus disease activity (HDA) by 75-93% in patients with SLE. These findings could guide clinicians to individualize HCQ doses to achieve target blood levels within this range to maximize efficacy, while balancing safety.

and dose-dependent reductions in serum total IgG levels and anti-AChR IgG autoantibodies (Figure 1), as compared to placebo. The safety and pharmacodynamic data from Vivacity-MG support the hypothesis that nipocalimab has the potential to treat pSS through lowering pathogenic IgGs. As such, we developed a phase 2, multicenter, randomized, placebo-controlled, double-blind study enrolling adults with moderately-to-severely active pSS. The pSS study consists of a 26-week screening period, a 24-week double-blind treatment period, and a 6-week follow-up period. Participants are randomized 1:1:1 to treatment every 2 weeks with intravenous nipocalimab (low or high dose), or placebo, through Week 22. The primary efficacy endpoint is change from baseline in Clinical European League Against Rheumatism Sjögren’s Syndrome Disease Activity Index (clinESSDAI) score at Week 24. Safety assessments include TEAEs, abnormal vital signs, and laboratory parameters.

**Conclusion:** Vivacity-MG demonstrated that nipocalimab has the potential to offer an important new and targeted treatment option for patients with IgG-mediated diseases. The ongoing phase 2 study evaluates the safety and efficacy of treatment with nipocalimab in patients with moderately-to-severely active pSS.

**Keywords:** Disease-modifying drug (DMARDs), Cell biology, Sjögren syndrome

**Methods:** Salivary gland tissues were harvested from pSS patients through labial or parotid biopsy. After tissue processing and vital organoids obtained, swelling assay and cell proliferation tests were performed after forskolin and apremilast application, compared to DMSO-treated controls. Immunohistochemistry evaluation on original salivary gland tissue and corresponding organoids was performed, by testing: alpha-amylase and AQP5 for acinar differentiation; EMA for ductal differentiation; calponin for myoepithelial differentiation and CK5 for basal differentiation; by testing: alpha-amylase and AQP5 for acinar differentiation; EMA for ductal differentiation; calponin for myoepithelial differentiation and CK5 for basal differentiation; CK14, cKit and CD34 as markers of progenitor/stem cells.

**Results:** After application of forskolin or apremilast, we observed organoid swelling after 30 minutes, compatible with positive functional status and enhancement of saliva production. DMSO-treated controls were instead unaffected. In 3 cases apremilast induced proliferation of the organoids (Figure 1). All the cases were positive for CK14, most of the cases for CK5. All the cases were positive for Amylase; its secretion, and thus functional status of organoids, was confirmed by its high concentration in the culture medium. A focal ductal differentiation was found in some cases, highlighted by EMA positivity. The more differentiated EMA positive areas were negative for CK14, showing a sort of “complementary staining”.

**Conclusion:** Our data confirm that, from pSS epithelium, differentiated cells that escape senescence and vital and functional organoids that recapitulate the development of original salivary glands can be obtained from different target tissues of pSS. The direct stimulating effect of PDE4 inhibitor apremilast on pSS human salivary organoids is reported, opening new perspectives on targeting oral dryness with drugs that combine secretagogue and immunomodulatory effects.

**HYDROXYCHLOROQUINE, WHICH REGULATES IFN, IS HIGHLY EFFECTIVE IN SLE WITH ELEVATED SERUM S100 PROTEIN**

**Keywords:** Systemic lupus erythematosus, Cytokines and chemokines

**R. Wakiya**, 1 H. Shimada, 1 K. Ueeda, 1 S. Nakashima, 1 T. Miyagi, 1 Y. Ushio, 1 K. Sugihara, 1 R. Mino, 1 M. Mizusaki, 1 K. Chuo, 1 T. Kameda, 1 H. Dobashi, 1

1Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan

**Background:** Serum S100 protein, a damage-associated molecular pattern factor, has been associated with interferon (IFN) [1]. In a previous study, we found that hydroxychloroquine (HCQ), which regulates IFN activity, modulates serum S100 protein in SLE patients [2].

**Objectives:** This study determined if the therapeutic effect of HCQ is altered in SLE patients with different serum S100 protein levels.

**Methods:** This single-center, prospective, exploratory study evaluated SLE patients with different serum S100 protein levels. The S100A8 and S100A9 protein levels were measured using DIA-SIGHT® (Beckman Coulter). The high and low groups were analyzed into three groups, namely, high, intermediate, and low, according to baseline serum S100A8 and S100A9 protein and adipokines (adiponectin, leptin, and VEGF-A, and MIP-1α) were measured by the multiplex Luminex assay, and cytokine changes after HCQ treatment were also greater than S100A8 low group. A trend similar to S100A8 significantly higher in the S100A8 high group. Cytokine changes after HCQ treatment were also greater than S100A8 low group. A trend similar to S100A8 significantly higher in the S100A8 high group.

**Results:** Serologic and demographic changes in SLEDAI and SLE-DAS scores before and 3 months after HCQ treatment were analyzed separately by baseline S100A8 levels. P-values were determined using Wilcoxon signed-rank sum test. 0M, 0 months; 3M, 3 months.

**Conclusion:** SLE patients with high serum S100 protein levels respond better to HCQ therapy. This finding suggests that serum S100 protein levels may predict the response to IFN inhibitor therapy.

**Background:** Activation of Type I interferons (IFNs) and a wide array of innate and adaptive immune mediators are hallmarks of the pathogenesis of systemic lupus erythematosus (SLE) and activation of IFN pathways correlates with disease activity [1]. In a phase 2 study of SLE patients, upadacitinib (UPA, Janus kinase inhibitor) given alone or in combination with belimumab (ABBV-599, Bruton’s tyrosine kinase inhibitor) resulted in significant improvement in disease activity as measured by British Isles Lupus Assessment Group-Based Combined Lupus Assessment (BICLA) and SLE Responder Index-4 (SRI-4) at weeks 24 and 48.

**References:**

The statistical analyses were conducted using the Mann-Whitney U test. *Nonparametric distributions are represented as medians (interquartile range).**

**Figure 1.** Association of serum S100 protein levels at baseline with SLE disease activity changes.

Methods: SLE patients (n = 205) were randomized to placebo (PBO); n = 75; UPA 30 mg QD; n = 62; ABBV-599; n = 68). At screening, patients were stratified by their SLE Disease Activity Index 2000 (SLEDAI-2K) score, corticosteroid dose (> 10-mg prednisone or not), immunosuppressant and IFN score. Proteomic analyses were performed on the plasma samples using a commercial proximity-extension immunomassay. A repeated mixed linear model was used to compare changes in biomarker vs PBO and Pearson’s correlation was tested to compare protein biomarkers, IFN score, and SLEDAI-2K score. All analyses were corrected for multiple testing using the Benjamini–Hochberg method. Enrichment analyses were performed to elucidate the biological pathways associated with changes in protein biomarkers.

Results: As expected, elevated IFN gene expression at baseline was associated with higher SLEDAI 2K disease activity scores, increased anti-double stranded DNA titers, and lower levels of complement components. Expression of serum proteins related to the IFN pathway, such as CXL10, sialic acid binding immuno- globulin-like lectin 1, IFN gamma, and ZBP1, positively correlated with the IFN score. Treatment with UPA monotherapy or the combination ABBV-599 significantly reduced the IFN gene scores compared with PBO at weeks 4 and 24 (P ≤0.001). Proteomic analyses revealed 301 protein biomarkers differentially modulated at weeks 2, 12, and 24 compared with PBO, including significant down-regulation of Type I IFN pathway proteins. There were additional impacts of UPA and ABBV-599 on T-cell–associated cytokines, B cells, macrophages, and innate response markers. These effects were similar with UPA and ABBV-599, suggesting that the main effect was attributable to activity of UPA.

Conclusion: These results suggest that the clinical benefit demonstrated by UPA in patients with SLE includes the modulation of Type I IFN with impact on several core pathogenic pathways involved in SLE. The main biomarker effects of UPA and ABBV-599 were driven by UPA.

POS1134 NOVEL APPROACH TO TREAT SYSTEMIC LUPUS ERYTHEMATOSUS, BY TARGETING THE “ROOT CAUSE”, B CELLS AND PLASMA CELLS, USING BCMA-CD19 COMPOUND CAR

Keywords: Autoantibodies, Systemic lupus erythematosus, Clinical trials

Y. Yuan1, S. He2, W. Zhang3, H. Zhang3, V. Destefano3, M. Wada3, K. Pinz2, G. Debeer5, Y. MA7, M. Wang5, F. Li1, M. Hong1, L. Ting1, C. Zou1, M. Wang5, L. Ding5, Y. Liang1, Y. MA7, W. Wang6, 2Zhongshan People’s Hospital, Department of Translational Medicine, Zhongshan, China; 2Zhongshan People’s Hospital, Department of Rheumatoid Immunology, Zhongshan, China; 3Peking University Shenzhen Hospital, Department of Hematology, Shenzhen, China; 4ICell Gene Therapeutics Inc., Research & Development Division, Stony Brook, United States of America; 5iCAR Bio Therapeutics Ltd, Research & Development Division, Zhongshan, China

Background: Systemic lupus erythematosus (SLE) is a heterogenous multi-systemic disease characterized by sequential localization of autoantibodies produced by the “root cause”, B and plasma cells. Autoimmunity depletion has been attempted by targeting B cells, however no such treatment addresses both B and plasma cells.

Objectives: We assess the safety and efficacy of dual resetting B and plasma cell populations using our novel BCMA-CD19 cCAR T (cCAR) in an open label phase I clinical trial.

Methods: We constructed a cCAR composed of a complete BCMA-CD19 fused to a complete CD19-CAR, separated via self-cleaving P2A peptide. The cCAR functional activity was assessed in co-culture assays with multiple cell lines and mouse models. T cells from peripheral blood obtained via apheresis were transfected to create cCAR. Cessation of steroids and immunosuppressing medications was followed by conditioning. Patients received monthly IgG until B cells recovered. Patients were dosed from 1.5x10⁹ cCAR cells/kg body weight and monitored. P1 and P2: 20-year history of managed SLE and received cCAR as compassionate use for B cell lymphoma. P1 and P2 achieved complete remission (CR). After 1-year follow up demonstrated CR of SLE, hospital approved additional SLE/Lupus Neprithis (LN) patients for treatment. Baseline Characteristics: 12 patients received cCAR therapy between 2023. P1 was male, P2 female. Ten of 12 were female. P1 and P2: SLEDAI-2K score 4, and 8, respectively. Patient 3-12: SLEDAI-2K baseline score mean 11 range 6 to 16. All of patients (3-12) had LN on kidney biopsy between IV to V with failure of standard therapy.

Results: Safety: Overall cCAR has been well tolerated to date. There have been no severe adverse events (SAE) or infections attributed to cCAR, no CRES and no CRS above Grade 1. All patients with >3 weeks follow up had a mild fever (CRS grade 1) which resolved with supportive care. Onset of mild fever occurred between days 3 to 14 and resolved within a week of onset. Efficacy: B cells were entirely depleted in peripheral blood 3-14 days post cCAR. Three patients treated >6 months in CR (SLEDAI-2K = 0, all autoantibodies negative, and normal complement). P1 and P2 maintain drug free CR and no autoantibodies post-cCAR approximately 40 and 20 months respectively. All B cells recovered within 2-6 months with no indications of relapse. At ≥1-4 months post-treatment 9 patients were negative for, anti-dsDNA autoantibody, anti-nuclear autoantibody, anti-SSA/Ro52 autoantibody, anti-SSA/Ro60 autoantibody, anti-ribosomal P, and anti-U1-snRNP Among patients rapid improvement within 1 month after cCAR, mean SLEDAI-2K dropped from 8.7 mean at baseline to 2 at 1 month (7 patients no symptoms), and mean drop to 0.88 within 6 months (9 patients no symp- toms). All patients achieved 100% response and are maintaining medication free recovery (no immunosuppressors or glucocorticoids). An immune “reset” was confirmed via flow cytometry showing that most of recurring cells are naïve B cells, and further observed in BCR deep sequencing (patients 3-4), whereby IgG and IgA clonotypes are absent and non-class-switched BCR repertoires are greater than 95% IgM heavy chain.

Conclusion: These data on the 12 patients treated with cCAR demonstrate that the intervention is well tolerated. Initial data suggests immune system “reset” with long-term remission is possible as cCAR treats the “root cause” of disease by depriving autoreactive antibodies produced by plasma cells and memory B cells. This approach can be extended to other B and/or plasma cell mediated autoimmune disorders. The full dataset will be updated at the meeting.

POS1135 EFFECT OF IMMUNOMODULATORY THERAPIES ON ANTIPHOSPHOLIPID ANTIBODIES TITERS IN CHILDREN WITH ANTIPHOSPHOLIPID SYNDROME

Keywords: Anti-phospholipid syndrome, Autoantibodies

P. Morán Álvarez1, E. Marasco1, V. Messia1, F. De Benedetti1, C. Bracaglia1

1Ospedale Pediatrico Bambino Gesù, Pediatric Rheumatology, Rome, Italy

Background: Pediatric Antiphospholipid Syndrome (APS) is an autoimmune disease characterized by venous and/or arterial thrombotic events (TE) associated with 2 consecutive positive determinations (at least 12 weeks apart) of antiphospholipid antibodies (aPL), IgG/IgM anticardiolipin (aCL), IgG/IgM [2-glycoprotein I (a2GPI)] and/or lupus anticoagulant (LA). Recent data suggests that aPL levels may decrease over time due to the natural history of the disease or to treatments. Therefore, monitoring of aPL levels may represent a strategy to evaluate disease activity or response to therapies.

Objectives: To investigate the trend over time of aPL titers in children with APS, comparing patients under immunomodulatory therapies and those without them.

Methods: A descriptive, observational, cross-sectional study was carried out in children with APS. aPLs testing was carried out in all patients from diagnosis every 3-4 months for 2 years. Inferfer Gene Signature (IGS) was assessed as described by Crow[1]. Laboratory parameters, clinical and demographic data was retrieved and analyzed. Statistical analysis was performed with software R_v.4.0.3.
Results: Sixteen children with a diagnosis of APS were included in this study. The median age at disease onset was 11.5 years (range: 6 months – 17 years) and 62.5% were female; 87.5% Caucasians. Thirteen patients (81.2%) had a diagnosis of primary APS and 3 (18.8%) out of 16 of secondary APS. Regarding clinical manifestations, 11 children developed at least one TE (7 arterial and 5 venous). Cerebral territory was the most frequently involved with 5 thrombosis, followed by 3 deep vein thrombosis, 1 pulmonary thromboembolism and 2 arterial renal thrombosis. Most of the patients received an antiaggregant and/or anticoagulant therapy (13 and 8 patients, respectively). However, 1 patient presented a new TE after the antiaggregant withdrawal. A total of 12 (75%) children developed at least one non-criterion manifestation: 7 patients (44%) cardiac (Libman-Sacks endocarditis or valvarular heart disease), 7 patients (44%) neurological (chorea or white matter lesions), 6 patients (37.5%) hematological (thrombocytopenia, hemolytic anemia or Evans syndrome) and 1 patient (3.8%) a renal thrombotic microangiopathy. Related to immunological parameters, 4 (25%) were positive for only 1 aPL, 5 (42%) for 2 aPL subtypes and 7 (44%) for all 3 aPL subtypes, showing the highest rates of IgG a2GP (87.5%) and IgG aCL (81.25%). Lower rates were identified for LA (44%), IgM aCL (18.7%) and IgM a2B2GP (12.5%). Four (25%) had ANA positivity (3 secondary and 1 primary APS). Regarding treatment, 13 children (81.25%) received at least one immunomodulatory drug (13 patients mycophenolate; 4 rituximab) and 3 (18.7%) were not treated with them. During the 2-year-follow-up, 11 patients (68.8%) showed a reduction of aPL titer compared to the onset, with becoming 9 negative (56.3%) at the end of follow-up (Figure 1A). Of those who were negative, 8 children were under immunomodulatory therapies and only 1 did not receive any treatment. Five patients (31.2%) showed stable titers of aPLs during follow-up. Of them, 2 were not treated with immunomodulatory therapies and 2 were under mycophenolate but with poor compliance (reduction of titers with the restart of therapy were observed). We also evaluated the presence of the IGS in 11 patients with APS for whom a whole blood RNA sample was available: the IGS was positive in 9 (81.8%) of 11 children (7 with primary APS and 2 with secondary APS).

Conclusion: Our data suggest the possible effect of immunomodulatory therapies in reducing antibody titers in APS. Therefore, it may represent a strategy to control the disease activity leading to a better prognosis. Further studies are needed to confirm and expand our data.

POS1138 DISEASE-MODIFYING EFFECT AND LONG-TERM SAFETY DATA OF BELIMUMAB IN PATIENTS WITH SLE: A SINGLE CENTRE RETROSPECTIVE ANALYSIS

Keywords: Systemic lupus erythematous

M. Okada1, T. Nakai1. 1St. Luke’s International Hospital, Immunno-Rheumatology Center, Tokyo, Japan

Background: Disease modification is an important concept for minimizing disease activity with the fewest treatment-associated toxicities when managing SLE. Belimumab has been used as a maintenance therapy for SLE; however, data on its disease-modifying effects are scarce.

Objectives: Therefore, we aimed to investigate the disease-modifying effects of belimumab in SLE patients.

Methods: This single-centre retrospective cohort study included SLE patients treated with belimumab at our institution. We analysed the changes in flare-rate ratio, lupus low disease activity state (LLDAS) achievement rate, glucocorticoid dosage, SLICC/ACR damage index (SDI) score, and drug retention rate after belimumab initiation.

Results: Of the 567 patients with SLE followed up in our hospital, 95 used belimumab and to 92 were included in the study. Fifty-two weeks after initiating belimumab, the flare rate decreased (82.6% to 14.1%) (p<0.01). At week 52 and day 1,000 after initiation of belimumab, >70% and approximately 90% of the patients achieved LLDAS, respectively. Belimumab administration also significantly decreased glucocorticoid demands, and at the end of the study period, 68.5% of patients achieved prednisolone ≤5 mg/day and 22.8% achieved glucocorticoid discontinuation. Furthermore, most patients were free of SDI progression (week 52, ±95%; end of study period, almost 90%), and belimumab showed a high drug retention rate (week 52, 90%; day 1000 after initiation >80%).

Conclusion: Most patients on belimumab achieved LLDAS, decreased flare rate and glucocorticoid demand, and a stable trend of SDI after its induction. Furthermore, belimumab had a high drug retention rate. Therefore, the introduction of belimumab may be a key element in disease modification.

Results: The previously developed population pharmacokinetic model for UPA showed that UPA pharmacokinetics were comparable in subjects with SLE and RA. A one-compartment model with a proportional error model best described the pharmacokinetics of ELS. Exposure-response analyses for efficacy based on logistic regression modeling demonstrated that at Week 24 and Week 48, statistically significant relationships were observed between UPA C_{avg} and SRI-4, SRI-4 and steroid dose ≤ 10 mg QD, and BICLA (Figure 1). No exposure-response trends were observed for ELS C_{avg} and the evaluated efficacy endpoints during the Week 24 analysis. Inclusion of ELS C_{avg} in the logistic regression models did not improve the model performance. Simulations based on the logistic regression models showed that UPA 30 mg QD is predicted to provide 8% to 17% higher response rates across the evaluated endpoints compared to UPA 15 mg QD. Exposure-response analyses for safety showed no clear trend for serious infections, lymphopenia, or neutropenia through Week 48. A shallow trend was observed for an increase in the percentage of subjects experiencing herpes zoster and a > 2 g/dL decrease in hemoglobin from Baseline at or through Week 48 with increasing upadacitinib C_{avg}.

Conclusion: Population pharmacokinetic and exposure-response analyses demonstrated that plasma exposures associated with UPA 30 mg QD were efficacious in subjects with SLE, while maintaining an acceptable safety profile. Addition of ELS, as part of ABBV-599, was not estimated to provide any additional efficacy benefit over UPA alone.

Keywords: Systemic lupus erythematosus, Kidneys.

W Bai1, M. Li1,1,1, 1Peking Union Medical College Hospital, Rheumatology, Beijing, China

Background: The effectiveness and safety of sirolimus for the treatment of systemic lupus erythematosus (SLE) and lupus nephritis (LN) have been shown in some studies. However, a comparison of sirolimus with standard of care (SoC) for LN patients has not been reported.

Objectives: To compare the effectiveness and safety of sirolimus versus mycophenolate mofetil (MMF) for LN treatment.

Methods: A real-world cohort study based on the Chinese SLE Treatment and Research (CSTAR) registry was conducted. Excluded patients with LLDSAS (lupus low disease activity state) or remission at baseline. LN patients who were prescribed sirolimus or MMF were enrolled. Propensity score matching was used to ensure equivalent disease conditions. SLE and LN disease activity indices, serological parameters, steroid doses, and adverse events were compared between the two groups at 3-month, 6-month, and 12-month visits.

Results: Data from 53 patients in each group were analyzed. The clinical effectiveness of sirolimus, including the proportion of patients with LLDSAS/remission, or clinical response (SLEDAI-2K reduction groups at 3-month, 6-month, and 12-month vSystemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) scores, physician’s global assessment (PhGA) scores, the remission of LN, the change of 24 hours urine protein level, and the steroid tapering effect, were equivalent to those of MMF (P>0.05). Greater improvements in complement levels were observed in the sirolimus group than the MMF group at 3, 6, and 12 months. Ten adverse events in the sirolimus group and one in the MMF group were recorded. None was severe or led to drug discontinuation.

Conclusion: Sirolimus was as effective as MMF in the treatment of LN and glucocorticoid tapering. Sirolimus had better effects on serological improvement. Sirolimus was well tolerated in LN patients.

BACKGROUND: Thrombocytopenia is a common manifestation associated with the presence of antiphospholipid antibodies (aPLs).

OBJECTIVES: To investigate the efficacy and safety of tacrolimus treatment in aPLs associated thrombocytopenia and to evaluate potential clinical factors affecting treatment response.

METHODS: This is a single-center observational prospective study. Patients with aPLs associated thrombocytopenia were recruited. Patients with systemic lupus erythematosus (SLE) related major organ involvement were excluded. Treatment response, adverse effects, bleeding events were monitored.

RESULTS: A total of 61 patients were enrolled from Jan 2016 to Apr 2022 with a median treatment duration of 22 months. The response characteristics are summarized in Table 1. The overall response rate was 80.3% (n = 49), including 49.2% of complete responses (n = 30). Compared to commonly used second line therapy for immune thrombocytopenia like eltrombopag and rituximab, a total of 30 patients (n = 30) were treated with tacrolimus at a median concentration of 5.9 (SD 3.6) ng/ml. The overall response rate was 80.3% (n = 49), including 49.2% of complete responses (n = 30).

CONCLUSION: This study suggests that tacrolimus has adequate efficacy and is well tolerated for aPLs associated thrombocytopenia. Patients with mild to moderate SLE might benefit the most from tacrolimus treatment.

SPANISH NATIONAL REGISTRY OF BELIMUAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Registries, Systemic lupus erythematosus

Background: Belimumab (BLM) is a monoclonal antibody that inhibits B-lymophocyte stimulating factor (BlyS) approved as a specific treatment for systemic lupus erythematosus (SLE) in 2011. We present the experience with BLM in a Spanish cohort with more than 460 patients.

Objectives: To describe demographic characteristics, efficacy and safety of BLM in patients with SLE in Spanish population since its approval. Methods: Descriptive, retrospective, multicenter study in patients diagnosed with SLE according to EULAR/ACR 2019, SLICC and/or ACR 1997 diagnostic criteria. Data regarding SLE patients treated with BLM were collected from medical records (2011-2022). Demographic features, efficacy, laboratory variables, SLEDAI, renal involvement, steroid dose, administration routes and safety were assessed. To see whether a trend in BLM prescription had changed or not over time, two periods of time were analyzed: 2011-2016 (period1) and 2017-2022 (period2).

Results: Baseline characteristics of patients are summarized in Table 1. A total of 462 patients (36 hospitals) were included, 50.9% were on intravenous (IV), 34% on subcutaneous (SC) and 15.1% switched from IV to SC route. The median number of pre-BLM csDMARD use was 2.0 (2.0-3.0), being hydroxychloroquine (HCQ) the most frequently used (94.5%), class III (21%) and class V (16%) the most frequently reported. After BLM, 73.3% of these patients improved (median proteinuria of 0.2 g/day (0.1-0.7). In period1, 100 patients started BLM compared to 362 in period2. The median time from SLE diagnosis to BLM begin was 7.1 (4.0-13.7) and 6.2 (2.1-14.4) years in period1 and period2, respectively (p=0.454). We found a trend to use more csDMARD before BLM treatment in period1: 2.5 (2-3) vs. 2 (2-3) (p=0.088). A total of 143 (30.5%) patients discontinued treatment mostly due to inefficacy (55.9%) and infections (11.9%). In fact, 116 patients developed infections, mostly mild; 2 patients died, 16 had COVID-19 and 4 patients developed tumors requiring discontinuation of the drug.

Conclusion: In our cohort of SLE patients in a real-world setting, BLM has been effective, safe and seems to be a good choice to treat renal involvement.

REFERENCES:
Potential of zetomipzomib was demonstrated by reduction of uCD163, which was strongly correlated with UPCR improvement at W13, W25 and W37 (Figure 1). For the thirteen patients who consented to urine biomarker analysis, baseline 24-hour UPCR was: mean=2.8 mg/mg, median=1.8 mg/mg, SD=3.3, range 0.93-13.4; uCD163: mean=1.7 mg/mmol, median=0.97 mg/mmol, SD=2.3, range 0.28-8.9. ROC analysis results from the MISSION study suggests that LN patients with uCD163 values of ≤0.13 at W13 and ≤0.09 at W25 are more likely to achieve a CRR at W25 and W37 following treatment with zetomipzomib (Table 1).

Conclusion: This post-hoc analysis of zetomipzomib data generated from the MISSION Ph2 study suggests that in patients with proliferative LN, uCD163 levels might predict CRR achieved up to 3 months later and could therefore potentially help to guide optimal therapy. Further evidence is needed from larger randomized LN trials with zetomipzomib to confirm the utility and limits of uCD163 as a predictive biomarker.

DOI: 10.1136/annrheumdis-2023-eular.2650
Background: Belimumab (BLM) is a recombinant human IgG1 monoclonal antibody that inhibits B-cell activating factor. It is approved for the treatment of systemic lupus erythematosus (SLE). It is effective in reducing disease activity, flares, damage prevention and also as a steroid-sparing agent. A treat to target (T2T) approach in the care of SLE patients is important in terms of improving short and long-term outcomes.

Objectives: To evaluate belimumab (BLM) effectiveness in SLE patients from a Spanish multicenter registry.

Methods: A longitudinal retrospective multicenter cohort including SLE patients treated with belimumab from 18 Spanish rheumatology departments. Demographic, clinical and serological data were collected at baseline, 6, 12 and in the last visit available. Changes in SLEDAI-2K; LLDBS and DORIS 2021 states and global response according to physician criteria were compared between visits, as well as changes in damage and glucocorticoids used. T-test was used for numerical variables and the Fisher’s test for categorical variables.

Results: 324 patients were included: 295 (91%) females with a mean (±SD) age of 42.4 (±12.9) years. Mean follow-up was 3.8 (±2.7) years and mean time with BLM was 2.7 (±2.4) years. At baseline, mean SLEDAI-2K was 10.4 (±5.25), 68.2% had elevated anti-double-stranded DNA (anti-dsDNA) antibodies and 69.8% had complement consumption. BLM was initiated concomitant to other DMARDs in 67.9% (n=220) of patients. Mean reduction in SLEDAI-2K score was 5.0 (±5.1), 6.1 (±5) and 7.3 (±3) points at 6, 12 months and in the last visit; respectively (p<0.05 for all comparisons). Rates of achievement of LLDBS, DORIS and clinical response according to physician criteria, significantly increased from baseline to 6, 12 months, and to the last visit (Table 1). Anti-dsDNA antibodies and inflammatory markers (ESR, CRP), significantly decreased from baseline to 6, 12 months and in the last visit. Complements increased over the follow up but without statistical significance. A total of 107 (45.9%) patients discontinued GC. At 6 months, 58.9% (n=155) of patients reduced the dose of GC with respect to baseline and 72.8% (n=131) of patients did it at the last visit. Mean (±SD) prednisone dose was significantly reduced over the visits: 12.3 (±3.96); 7.42 (±3.56); 5.8 (±4.42) and 4.7 (±3.7) mg/day at baseline, 6 and 12 months and in the last visit, respectively. Median (IQR) SDI score at the end of the observation period did not change from baseline visit: 0 (0-1) and 0 (0-1), respectively (p=0.97). Neither were changes observed in the percentage of patients with damage between the beginning and the end of the observation period: at baseline 47.5% (n=162) patients presented damage and, in the last visit, 45.6% (n=99).

SLEDAI: Systemic Lupus Erythematosus Disease Activity Index, cSLEDAI: clinical SLEDAI; LLDBS: Lupus Low Disease Activity State, DORIS: Definition of remission in SLE. *p<0.05

Figure 1. Rates of therapeutic targets attained by patients in treatment with Belimumab.

Conclusion: Real-world data of SLE patients confirm belimumab efficacy in real world, reducing clinical and serological activity in the short and medium-term. Add-on therapy with BLM leads to high rates of LLDBS and DORIS at 6 months, that continue increasing over time. BLM has an important GC sparing effect and prevents organ damage accrual. All these data shows that BLM is useful to achieve the therapeutic goals of a T2T strategy.

POS1145 FACTORS ASSOCIATED WITH SURVIVAL AND DISCONTINUATION OF ANTIMALARIAL AGENTS IN THE CARE OF SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM A SWEDISH LONGITUDINAL REGISTRY

Keywords: Disease-modifying drug (DMARDs), Systemic lupus erythematosus (SLE), Antimalarial agents (AMA), Hydroxychloroquine (HCQ), Chlooroquine (CQ), Clinical Lupus Register in North-Eastern Gotland.

T_Walheim1, L_Wirentam1, E_Ennrman1, I_Parodi1, C_Sjowall1. 1_Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden; 2_Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden; 3_Orebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden

Background: Hydroxychloroquine (HCQ) and chloroquine, referred to as antimalarial agents (AMA), are cornerstone drugs in systemic lupus erythematosus (SLE), which inhibit type I interferon release via toll-like receptor binding and increasing the pH in plasmacytoid dendritic cell lysosomes [1]. AMA use has established benefits in SLE, such as improved prognosis and decelerated accrual of organ damage. Use of HCQ is safe for most patients and serious side-effects are uncommon, even during pregnancy. Medical therapy to prevent repeated disease flares is of essential weight in the treatment of SLE. However, it is well-known that non-adherence to prescription of AMA is a considerable problem [2].

Objectives: The aim of this cross-sectional study was to investigate the frequency of AMA prescription, and evaluate factors associated with ongoing use and discontinuation of AMA in a Swedish SLE population.

Methods: We retrieved data from the Clinical Lupus Register in North-Eastern Gotland (Swedish acronym: KLURING), a longitudinal research and quality registry, including all prevalent and incident cases of SLE in the Östergötland County from 2008 onwards. All included subjects fulfilled the validated 1982 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria and had been diagnosed from 1963 onwards. Factors associated with ongoing use and discontinuation of AMA were investigated using logistic regression analysis, Mann-Whitney U test and chi-square test.

Results: A total of 328 subjects were included in the analysis. The mean age at diagnosis was 40.0 years (range: 3–85; standard deviation [SD]: 17.7) and 85.7% were females. The mean SLICC/ACR damage index (SDI) score at last visit was 2.0 (range: 0–11; SD: 2.5). In total, 92.4% had used AMA at some point during their disease course (“ever” users; Table 1). Data from the last available visit indicated that 73.2% were currently prescribed AMA, exclusively HCQ, yielding a
daily mean HCQ dose of 228.0 mg (range: 100—400; SD: 71.0). Among individu-
als who had discontinued AMA, 25.9% had developed a contraindication, mostly
on ophthalmological basis (33.3%). Less common reasons were cardiac condi-
tions (19.0%) and renal failure (9.5%). Subjective side-effects were also com-
mon; the most frequently reported were gastrointestinal symptoms (n=20/37). 
Most common patient-related factor associated with discontinuation was inten-
tional non-adherence (e.g., low motivation; 8/11). Patients who had discontinued
AMA showed a higher SDI score at the last visit (mean: 2.9; SD: 2.8; mean fol-
low-up: 20.0 years) compared with patients on AMA (mean: 1.4; SD: 1.8; p=0.001;
mean follow-up: 15.3 years). Those who fulfilled the immunological disorder ACR
criterion (ACR-10) were more likely to continue on AMA (p=0.003). No significant
differences were found regarding gender or smoking status.

Conclusion: The vast majority of patients in KLURING had been exposed to
AMA, and approximately 25%, discontinued AMA therapy during follow-up. The
main reason for discontinuation was therapy-related factors, such as contrain-
dications and experience of side-effects. Above 50% of the reported side-effects
that led to discontinuation were gastrointestinal symptoms. The group of discon-
tinued AMA users accrued more damage over time.

LOW MOLECULAR WEIGHT HEPARINS INTERFERE 
WITH NEUTROPHIL ACTIVATION AND NET 
GENERATION IN HIGH-RISK PREGNANT PATIENTS 
WITH ANTIPHOSPHOLIPID SYNDROME

Keywords: Cell biology, Pregnancy and reproduction, Innate immunity

P. Rovere-Querini1, V. Canti1, A. D’angelo1, M. T. Castiglioni1, S. Rosa1, 
E. Manfredi2, B. Frascella3, V. D’alberti1, A. Manfredi1, N. Maugeri1, ERCSS 
San Raffaele Scientific Institute, Autoimmunity and Vascular Inflammation Unit, 
Milano, Italy

Background: Neutrophil activation and the generation of neutrophils extracellu-
lar traps (NETs) contribute to vascular damage and thrombosis in antiphospho-
lipid syndrome (aPS). We reported that Low molecular weight heparin (LMWH)
prevent neutrophil activation induced by P-selectin expressed by activated plate-
ets [1, 2] and jeopardize in healthy subjects the ability of neutrophils to generate
NETs and to mobilize granule contents [3].

Objectives: To investigate whether LMWH, used on empirical bases to in high-
risk patients, regulate neutrophil/platelet interaction in pregnant women.

Methods: Here we report preliminary data from a prospective monocentric study
in which the activation of platelets and neutrophils was assessed in sixteen preg-
nant women treated with LMWHs, with or without aPS at 12, 24 and 32 weeks of
gestation. Patients were studied again when feasible after pregnancy completion.
Sixteen healthy pregnant women, ten healthy women outside pregnancy and
ten women with Systemic Lupus Erythematosus outside pregnancy served as
controls.

Results: Platelets of pregnant healthy women were assessed, as assessed by the
increased expression of P-selectin and tissue factor. All patients successfully
completed the pregnancy. Abnormalities were evident at the pathological assess-
ment of the placenta despite the treatment with LMWHs. The treatment was
associated with significantly reduced: i) platelet/neutrophil interaction, as
assessed by heterotypic aggregates; ii) neutrophil expression of tissue factor; iii)
platelet expression of the prototypic DAMP; HMGB1; iv) accumulation in the blood
of byproducts of NET formation/catabolism, such as myeloperoxidase-DNA com-
plexes. P-selectin expression was, in contrast, unaffected.

Conclusion: The results indicate that neutrophil and platelet activation/interac-
tion, which may reflect detrimental intravascular immune events leading to preg-
nancy complications, abate in patients treated with LMWHs.

EFFICACY OF CENERIMOD IN PATIENTS WITH 
HIGH IFN-1 GENE EXPRESSION SIGNATURE 
AND HIGH ANTI-DSDNA ANTIBODY LEVELS: 
POST-HOC ANALYSIS FROM A PHASE 2 STUDY

Keywords: Clinical trials, Systemic lupus erythematosus

A. Askanase1, D. D’cruz2, K. Kalunian3, J. Merrill4, S. Navarra5, C. Cahuzac6, 
P. Cornelisse6, D. Strasser2, L. Trokan2, O. Berkani1, 1Columbia University, 
Medicine, New York, United States of America; 2Guy’s and St. Thomas’ Hospital, 
Rheumatology, London, United Kingdom; 3UCSD, Rheumatology, San Diego, 
United States of America; 4OMRF, Rheumatology, Oklahoma City, United States 
of America; 5University of Santo Tomas, Rheumatology, Manila, Philippines; 
6Idorsia Pharmaceuticals, Clinical Development, Atschwil, Switzerland

Background: Cenerimod is an orally active, selective sphinogine 1-phosphatase 
(SIP1) 1 receptor modulator under investigation for the treatment of systemic lupus 
erythematosus (SLE). The Phase 2 CARE study (NCT03742037) did not meet its 
primary endpoint after adjustment for multiplicity, but patients treated with cen-
erimod 4mg showed reduced disease activity versus placebo after 8 months.[1] 
Along with prior findings that type-1 interferon (IFN-1) activation is a robust bio-
marker of SLE disease activity and that an elevated IFN-1 signature associates 
with autoantibodies and more severe disease, cenerimod reduces plasma levels of 
IFN-a and leads to decreased circulating B and T cells in patients with SLE, 
suggesting effects on both innate and acquired immune responses.

Objectives: These post-hoc analyses evaluated the efficacy of cenerimod in 
subpopulations of patients with SLE.

Methods: CARE randomised 427 patients with SLE to once-daily cenerimod 
(0.5, 1, 2 or 4 mg) or placebo. At month (M) 6, patients receiving 4 mg ceneri-
mod were re-randomised to placebo or cenerimod 2 mg for the subsequent 6 
months, while all other groups continued their initially assigned treatment to 
M12. The primary endpoint was change from baseline to M6 in SLEDAI-2K 
score modified to exclude leukopenia (mSLEDAI-2K) due to the mechanism 
of action of cenerimod. Post-hoc analyses were performed in patients with 
high IFN-1 gene expression signature or anti-dsDNA levels ≥30 IU/mL. IFN-1 
gene expression signature was based on the expression of four genes (IFI27, 
RSAD2, HERC5, IFIT1).

Results: Primary results from the CARE study were presented at ACR 
2022.[1] The primary endpoint was not met (nominal P=0.0291 for cenerimod 
4mg vs placebo). At baseline, 207 patients (51%) in CARE had high IFN-1 
gene expression signature, including 36 (45%) and 40 (50%) randomised to 
cenerimod 4mg and placebo, respectively. Anti-dsDNA antibody levels ≥30 
IU/mL were noted in 86 patients (20%), including 21 (25%) and 15 (17%) for 
cenerimod 4mg and placebo, respectively. There was an association 
between high IFN-1 gene expression signature and high anti-dsDNA levels, with 
more than 75% of patients with anti-dsDNA levels ≥30 IU/mL having high 
IFN-1 gene expression signature. Reduction in mSLEDAI-2K from baseline to 
M6 for the cenerimod 4 mg group was greater in patients with high IFN-1 
gene expression signature versus the overall population (Figure 1A). Similarly, the proportion of SRI-4 responders at M6 
was higher in patients with high versus low IFN-1 gene expression signature.
HYDROXYCHLOROQUINE THERAPY ELECTROCARDIOGRAM IN PATIENTS WITH OPTIMAL CUT-OFF POINT FOR

(70% vs 41% for cenerimod 4 mg; 46% vs 43% for placebo). Patients with high IFN-1 gene expression signature treated with 4 mg cenerimod showed reduced IFN-α and anti-dsDNA levels at M6 versus baseline. At M6 resolution of alopecia was reported by more patients with high versus low IFN-1 gene expression signature (38% vs 26% for cenerimod 4 mg; 14% vs 7% for placebo), as were resolution of arthritis (57% vs 28% for cenerimod 4 mg; 38% vs 42% for placebo) and reduction in mucosal ulcers (80% vs 67% for cenerimod 4 mg; 41% vs 41% for placebo) on the mSLEDAI-2K. However, there was no treatment effect observed in rash.

**Conclusion:** Treatment with cenerimod 4 mg resulted in greater reductions of disease activity versus placebo in M6 in patients with high IFN-1 gene expression signature or high anti-dsDNA antibody levels at baseline. Cenerimod treatment also reduced levels of IFN-α protein and anti-dsDNA antibodies in these patients. Two Phase 3 studies of cenerimod 4 mg in SLE are underway.

**REFERENCES:**

**Objectives:** To assess the optimal cut-off point for electrocardiogram (ECG) in patients with SLE on HCQ therapy to prevent arrhythmic complications.

**Methods:** Single university hospital observational study of all consecutive SLE patients who had an ECG at baseline and at least one ECG at follow-up. New conduction disturbances were assessed by ECG, defined as atrioventricular block, bundle branch block or QT interval prolongation. ECGs were extracted from the medical record and interpreted at baseline and for 15.2 years (95% CI 3.5-15.2) of follow-up. We defined cumulative HCQ (cHCQ) as the total grams of HCQ that had been administered. A Receiver Operating Characteristic (ROC) curve analysis was performed to determine the optimal cut-off point for sensitivity and specificity.

**Results:** We studied 105 (93 female/12 male) SLE patients with a mean ± SD age of 61.8±14.9 years. The mean daily dose of HCQ in our sample was 256 mg per day (Table 1). The ROC curve showed a moderate diagnostic ability for new conduction disturbances with an area under the curve of 0.69 (95% CI 0.59 - 0.77) (Figure 1). The highest efficacy cut-off point was chHCQ: 409.7 mg (Sensitivity 70%, Specificity 100%) and the optimal cut-off point was chHCQ: 901 g (Sensitivity 85%; Specificity 52.9%). This cut-off point was reached with a mean HCQ treatment in our sample of 9.7 years. High grade atrio-ventricular block was found in 5 patients. In all of them the chHCQ dose was over 901g.

**Conclusion:** According to our study, 901 g of chHCQ dose is a good cut-off point for performing a protocolized ECG to rule out cardiac conduction disturbances in patients with SLE and chronic HCQ treatment. This is equivalent to 9.7 years of treatment with the mean HCQ dose use in our sample.

COMPARISON OF THE EFFICACY AND SAFETY OF TELITACICEPT VERSUS BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL CLINICAL PRACTICE: ANALYSES WITH PROPOsITY SCORE-BASED INVERSE PROBABILITY OF TREATMENT WEIGHTING

Keywords: Treat to target, Real-world evidence, Systemic lupus erythematosus

H. Jin1, Z. Chen1,2, 1The First Affiliated Hospital of USTC, Department of Rheumatology and Immunology, Hefei, China; 2University of Science and Technology of China, Division of Life Sciences and Medicine, Hefei, China

Background: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease characterized by aberrant expansion of B cells. The B cell-stimulating molecules, B cell activating factor/a proliferation-inducing ligand (BAFF/APRIL), are critical factors in promoting the proliferation and differentiation of B cells thus play a prominent role in the pathogenesis of SLE. There are two types of BAFF/APRIL-targeted biological agents being approved as an add-on therapy for patients with active SLE in China, including the BAFF/APRIL dual inhibitor, telitacicept and the BAFF inhibitor, belimumab. However, the differences of efficacy and safety between these two agents in real clinical practice has not been clarified.

Objectives: To compare the differences of efficacy and safety between the two types BAFF/APRIL inhibitors telitacicept and belimumab in the treatment of active patients with SLE.

Methods: Clinical features, laboratory data, SLE Disease Activity Index 2000 (SLEDAI-2K), treatment history, and adverse events (AEs) during the six months follow-up were collected. Propensity score based inverse probability of treatment weighting (IPTW) was used to reduce the selection bias.

Results: Active SLE patients who received telitacicept (N=52) and belimumab (N=77) from 2019 to 2022 at our rheumatology department were retrospectively reviewed. No significant differences were observed in patient characteristics between the two groups after adjustment by IPTW. Patients who received telitacicept have a significantly higher decrease of SLEDAI-2K score and Physician’s Global Assessment (PGA) score at 24 weeks (p<0.05). Consistently, there was a higher elevation of complement (C)3 and C4 levels at 4 and 12 weeks in telitacicept group (p<0.05). The telitacicept group acquire a higher frequency of primary efficacy renal response (PR) than belimumab at 12 weeks and no obvious differences were observed in complete renal response (CR) at 12 and 24 weeks according to the Belimumab International Lupus Nephritis Study (BLISS-LN) criteria. In addition, the improvement of anemia was better in the telitacicept group (p<0.05). Importantly, the telitacicept group had a lower incidence of AEs, including upper respiratory tract infections, diarrhea and leukopenia, than the belimumab group after IPTW (p<0.05).

Conclusion: Telitacicept showed a better efficacy and safety than belimumab for active SLE patients in a single center clinical practice. Further investigations in a larger cohort are required to testify these findings.

ULTRASOUND-DETECTED EROSIONS COULD PREDICT THE EFFICACY OF BELIMUMAB IN ARTICULAR SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: bDMARD, Systemic lupus erythematosus, Ultrasound

G. Orsini1, R. Bixio1, F. Mastropaolo1, A. Piccinni1, E. Favaro1, O. Viapiana1, G. Adam1, M. Rossini1, 1University of Verona - OAU Verona, Rheumatology Unit, Verona, Italy

Background: Articular involvement (69-95%) in patients with systemic lupus erythematosus (SLE) is traditionally considered non-erosive. SLE arthritis with radiographic erosions with or without rheumatoid factor (RF) and/or anti-citrullinated peptide antibody (ACPA) positivity is often described as “rhepus” and is considered an overlap between SLE and rheumatoid arthritis (RA). While radiographic erosions are shown in about 5-15% of the patients, ultrasound and magnetic resonance imaging could reveal erosions in up to 40% of patients with SLE.

Objectives: The aim of this study is to assess if the presence of ultrasound-detected erosions can predict the efficacy of belimumab, a B lymphocyte simulator (BlỹS) inhibitor, in the treatment of SLE-related articular manifestations.

Methods: We performed a spontaneous, monocentric, retrospective, and observational study. We enrolled patients with a diagnosis of SLE according to the 2019 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria with articular involvement treated with belimumab. Patients with ACPA- or RF-positivity, Jaccoud’s arthropathy, or radiographic erosions were excluded. We collected laboratory and clinical data from the electronic records. Joint disease activity was assessed at baseline, 3- and 6-months follow-ups (FU) using disease activity score on 28 joints based on C-reactive protein (DAS28-CRP). At baseline, all patients underwent an ultrasound examination of the wrist, metacarpophalangeal, proximal interphalangeal, and metatarsal-phalangeal joints. Erosions were defined according with the outcome measures in rheumatology (OMERACT) definition (at least 1 mm). Student’s T-test and Mann-Whitney’s U-test were used to assess differences between means and Fisher’s exact test to assess differences between proportions.

Results: We enrolled 23 patients (baseline characteristics in Table 1). Seven patients (30.4%) had bone erosions at baseline. They were generally older (61±16.1 vs 46.13±10.7 years, p=0.016), more frequently male (42.8 vs 6.2%, p=0.03), with higher C4 (0.19±0.17 vs 0.1±0.04 g/L, p=0.05) than patients without erosions. DAS28-CRP decreased significantly at 6-months FU (2.95±0.89 vs 2.26±0.48, p=0.01) only in patients without erosions, as shown in Figure 1. The majority of patients (73.9%) achieved remission at 6-months FU (DAS28-CRP criteria), with a significant difference between patients with and without erosions (42.8 vs 87.5%, p=0.045).

Conclusion: The presence of ultrasound-detected erosions could be predictive of a decreased efficacy of belimumab in articular SLE. A possible explanation is a rheumatoid-like articular phenotype, despite the lack of ACPA-positivity and radiologic erosions. Our findings could help expand the “rhupus” spectrum and highlight the possible role of different SLE phenotypes in the therapeutic response.

POS1151 THERAPEUTIC DRUG MONITORING OF AZATHIOPRINE AND TACRIMOLUS IN SLE PREGNANCIES: PRELIMINARY RESULTS FROM THE LEGACY COHORT

Keywords: Disease-modifying drug (DMARDs), Pregnancy and reproduction, Systemic lupus erythematosus

R. Farhat1,2, A. Mendez2,3,4, I. Malhamé2,3,4, J. Y. E. Lee2, L. Ciofani2, S. Bernatsky2,3,4, E. Vinet2,3,4. McGill University, Division of Experimental Medicine, Faculty of Medicine and Health Sciences, Montreal, Canada; 2Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation (CORE), Montreal, Canada; 3McGill University, Department of Medicine, Faculty of Medicine, Montreal, Canada; 4McGill University Health Centre, Division of Rheumatology, Division of Clinical Epidemiology, Department of Medicine, Montreal, Canada; 5MUHC – McGill University Health Centre, Division of General Internal Medicine, Department of Medicine, Montreal, Canada

Background: Pregnant SLE women still face an unacceptably high risk of maternal and fetal morbidity, particularly when their disease is active. How to personalize SLE therapies to optimize pregnancy outcomes remains unknown. Though guidelines strongly recommend azathioprine (AZA) and tacrolimus (TAC) in pregnancy (non-pregnant populations). We defined patients as non-adherent if they had undetectable or barely detectable levels despite appropriate dosing.

Results: Of 64 LEGACY pregnancies enrolled in Montreal, 23 (36%) and 6 (9%) were prescribed AZA and TAC, respectively. Among those prescribed AZA, only 9% had therapeutic levels, while 91% were sub-therapeutic or non-adherent. Compared to those with therapeutic levels, pregnancies with sub-therapeutic or non-adherent AZA levels were more likely to occur in women of non-Caucasian ethnicity/race, on steroids, with longer SLE duration, and with prior lupus nephritis (Table 1). Among those prescribed TAC, 50% (3/6) had therapeutic levels, while 33% (2/6) and 17% (1/6) were sub-therapeutic and supra-therapeutic, respectively.

Conclusion: We observed that most SLE pregnancies prescribed AZA had sub-therapeutic levels, with nearly a third identified as non-adherent. Pregnancies with lower AZA and TAC levels may be less likely to achieve LLDAS. Despite low numbers, our preliminary results suggest the value of personalized drug monitoring as a novel approach to precision medicine in pregnant SLE women, that might improve efficacy, safety, and adherence in a high-risk population.

Background: The approval of two new drugs, belimumab and voclosporin, in lupus nephritis (LN) over the last years has raised questions regarding their place in the therapeutic algorithm of LN. Their use in initial regimens or in refractory/relapsed disease depends on disease outcomes with current standard of care therapies (SoC). To calculate EULAR/ERA-EDTA renal response rates with SoC therapies at 3, 6 and 12 months, as well as rates of successful tapering to the recommended glucocorticoid use at 6 months in real-life clinical settings.

Methods: Combined retrospective and prospective (2015–today) cohort study of patients with histologically confirmed LN. Demographic, clinical, and laboratory data, as well as treatment administered at baseline and respective changes every 3 months, were collected. Renal response rates according to EULAR/ERA-EDTA goals of treatment were calculated: (at 3 months: proteinuria reduction by 25%, 6 months: 50% reduction to subnephrotic level, 12 months: proteinuria < 500–700mg/24h, all with stabilization or improvement in kidney function). The percentage of patients who received IV methylprednisolone (total recommended dose 500-2500mg), as well as mean prednisone dose per day at baseline (recommended dose 0.3–0.5mg/kg in class III and class IV and <5mg/day at 3 months in class V) and thereafter (<7.5mg/day at 6 months in class III and class IV and <5mg/day at 3 months in class V). We also calculated the percentage of patients who had tapered prednisone to the recommended daily dose by 6 months.

Results: 110 patients were included, 83 completed a 12month follow up [81.8% female, median (IQR) age 36.5 (23) years]. One third (33.6%) of patients had nephrotic range proteinuria at diagnosis. Histologically, 16.7% had LN class III, 33.3% class IV, 18.5% class V and 27.8% mixed class (III/IV + V). With SoC therapy [initial therapy: 48.1% cyclophosphamide (CYC), 32.4% mycophenolic acid (MPA), followed by maintenance therapy], 76.7%, 82.6% and 71.1% achieved glucocorticoid use at 3, 6 and 12 months, respectively. No differences between CYC and MPA groups regarding response rates were noted. All patients received IV methylprednisolone at baseline (median (IQR) 2.0 (3.0) mg).

Regarding glucocorticoid use, in proliferative classes (III/IV), median (IQR) prednisone starting dose was 40.0 (20.0) mg/day, corresponding to a mean (SD) dose of 0.63 (0.27) mg/kg/day. At 6 months, median (IQR) daily dose was 10.0 (10.0) mg. In class V LN, median (IQR) daily starting dose was 32.5 (20.0) mg and 15.0 (10.0) mg at 3 months.

Conclusion: Although a significant number of LN patients achieve treatment target between 3-12 months, approximately 25-30% fail. Moreover, prednisone doses used in LN tend to be higher than those recommended by EULAR/ERA-EDTA. Predictive factors associated with suboptimal response can help to shape therapeutic decisions identify patients that may benefit from early use of novel therapies.

APPLYING THE WORKING DEFINITION OF THE DISEASE MODIFICATION CRITERIA TO SYSTEMIC LUPUS ERYTHEMATOSUS TREATMENTS FROM THE PUBLISHED LITERATURE

Keywords: Organ damage, Kidneys, Outcome measures

11University of California San Francisco School of Medicine, Department of Medicine, San Francisco, CA, United States; 12GSK, Global Medical Affairs, Stevenage, United Kingdom; 13GSK, Specialty Care, Global Medical Affairs, Collegeville, PA, United States; 14Amsterdam Rheumatology and Immunology Center and Amsterdam University Medical Centers, Department of Rheumatology, Amsterdam, Netherlands; 15University of Toronto, Professor Emeritus, Department of Medicine, Toronto, ON, Canada

Background: In our recently published working definition, we proposed that disease modification in systemic lupus erythematosus (SLE) requires ‘minimising disease activity with the fewest treatment-associated toxicities and slowing or preventing organ damage progression’[1].

Methods: Based on a review of a selection of clinical trial (n=31) and observational (n=42) data publications for 16 SLE medications across different treatment classes and, the authors’ clinical experience, we evaluated their disease modification potential per the non-renal disease activity and organ damage criteria at three time points (Table 1).

Results: Nine of the 16 SLE treatments met at least one disease modification criterion across all time points (Table 1). Hydroxychloroquine improved overall survival at >5 years, suggesting long-term disease modification, but with data per specific criteria lacking[2]. Belimumum met two of the three disease modification criteria at the first two time points, but was the only treatment to meet criteria at >5 years based on the current literature. While steroids unabiguously decrease disease activity at early timepoints, at doses higher than 7.5mg/day the negative impact on damage accrual might hamper their disease modification potential >5 years.

Conclusion: This is the first attempt to determine which of the currently used treatments in patients with SLE fulfil the disease modification criteria at different time points. Belimumab and hydroxychloroquine showed evidence of disease modification up to and beyond 5 years; evidence for many other SLE therapies was incomplete, particularly at >5 years of follow up. The use of multiple agents, differences in study designs, patient populations, and definitions of treatment response pose challenges in categorising treatments as disease modifiers. Future studies will evaluate the minimum number of criteria required to designate disease modification at each of the three time points so that disease modification can be considered in the care of patients with SLE and in SLE trial design.

* criterion met; † insufficient evidence in the literature to meet the specific criterion, but strong general indications of met criterion; ‡ inconclusive; ○ data not available in the literature

**Notes:**
- **S7.5 mg/day per 2019 EULAR SLE treatment guidelines and LLDAS: 55 mg/day per DORIS remission definition**
- **Data were available in the literature but the criterion was not met**

**Key Points:**
- The primary endpoint was time to treatment failure compared to historical controls from the BOLD study which followed the same protocol but without treatment after initial steroids.
- Response was also evaluated at six months by the SLE Responder Index (SRI-4) or the BILAG-based Combined Lupus Assessment (BICLA).
- Before and during treatment, Pax Gene tubes were collected, and RNA sequenced, using the same methods for healthy control samples. To maximally discriminate clinical responders from non-responders by baseline gene expression patterns in a small, heterogenous population, the data were combined with modules (metagenes) comprised of differentially expressed genes (DEGs).

### Disclosure of Interests

### Background
Belimumab, which targets the B Cell activator and survival factor BLYS, is an approved treatment for systemic lupus (SLE) and has demonstrated efficacy in multiple clinical trials around the world. Nevertheless, like other SLE treatments, belimumab can have disappointing results in a significant proportion of this heterogenous population, a problem further complicated by the unpredictable impact of various combination treatments used with belimumab in trials and clinical practice.

### Objectives
- Examination of gene expression variables in SLE patients prior to belimumab treatment with limited background medications in order to distinguish those who subsequently respond from those who do not.

### Methods
- A prospective open-label study of belimumab was conducted in 24 SLE patients with active but non-organ threatening disease, who were required to withdraw other immune suppressants (only antimalarials or low dose steroids allowed). At baseline, patients were given optional steroid injections for temporary relief, then followed for six months on intravenous belimumab (10 mg/kg).

### Results
- Of 24 patients entering the study, 20 completed 6 months of treatment. The mean survival time without flare, treatment change, or study withdrawal was 18.4 weeks (CI 15.3-21.5) compared to the 41 BOLD participants with mean survival 9.829 weeks (CI 0.999-7.871) (p<0.001 by log rank test). At 6 months, 14 patients who received belimumab (58%) and 1 from the BOLD study (2.4%) remained free of flare. The SRI-4 was met by 7 patients in this study (29.2%), the BICLA by 9 (37.5%). SRI-4 response was used as the basis for modeling two metagenes comprised of the 25 most upregulated and 25 most downregulated genes at baseline in belimumab responders as compared to non-responders. There was no overlap between the metagene scores of responders vs non-responders (Figure 1). After 3 months of treatment with belimumab all metagene scores remained free of flare. The SRI-4 was met by 7 patients in this study (29.2%), and most did not flare for at least six months. A composite metagene model has been identified as a potential predictor of belimumab response. Confirmation studies should be prospectively conducted.

### Conclusion
- When background immune suppressants are excluded, belimumab achieves SRI 4 or BICLA response for some patients, and most do not flare for at least six months. A composite metagene model has been identified as a potential predictor of belimumab response. Confirmation studies should be prospectively conducted.

IMPACT OF HYDROXYCHLOROQUINE ON INTERFERON PATHWAY EXPRESSION OF SLE PHENOTYPIC SUBSETS IN THE ABSENCE OF BACKGROUND MEDICATIONS

Keywords: -omics, Systemic lupus erythematosus, Biomarkers

C. Mowery1,2, M. Smith3, K. Thomas4, S. Macwana5, W. Dejager1, S. Kamp1, B. Parrish6, A. Affrini7, T. Aberle3, J. T. Merrill8, J. Guthridge4, J. A. James1, 1Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology, Oklahoma City, United States of America; 2University of Oklahoma Health Sciences Center, School of Medicine, Oklahoma City, United States of America

Background: Chronic activation of interferon (IFN) pathways is a key driver of immune dysregulation in SLE. Hydroxychloroquine (HCQ) inhibits toll-like receptors 7 and 9 in plasmacytoid dendritic cells resulting in decreased release of interferon alpha[1]. Studies in SLE are limited by patient heterogeneity and the superimposed complexity of combined medications they receive.

Objectives: This project compared activation of Type I and II interferon (IFN) pathways in SLE patients with discrete immune phenotypes who were taking hydroxychloroquine or not (HCQ vs No Rx) without corticosteroids or any other SLE treatments.

Methods: 133 samples from 85 SLE patients (70 on HCQ, 63 on No Rx) and 37 healthy controls were studied. Characteristic clusters of patients who shared immune activation patterns were identified by Random Forest modeling of soluble mediators and gene co-expression module scores, as previously reported[2,3]. Samples from four of these immunologic clusters (C1, C4, C3, and C6), all with elevated expression of IFN modules (M1.2, M3.4, and M5.12) were examined for impact of HCQ on IFN pathway expression and compared to clusters with lower immune activation patterns. Dual samples from each of 21 patients when on HCQ vs No Rx at different timepoints were also examined.

Results: As expected, expression of IFN pathway modules were increased in the overall SLE population vs healthy controls, driven by patient phenotype clusters 1,3,4 and 6. All IFN modules were decreased in SLE patients on HCQ vs No Rx (M1.2 p=0.035, M3.4 p=0.009, and M5.12 p=0.005), again promulgated by changes in clusters 1,3,4 and 6 (Figure 1). In multilinear regression modeling, HCQ had independent effects on M1.2 (p=0.0004), M3.4 (p < 0.001), and M5.12 (p < 0.001) after adjusting for cluster and race. Age and SLEDAI score had no impact of HCQ on IFN pathway expression and compared to clusters with lower expression (Clusters 2,5,7)

Background: Each lupus nephritis (LN) flare causes nephron loss that equals a decade or more of reduction in renal function lifespan, making prompt initiation of therapy imperative and prevention of flares even more desirable. Identification of readily available signals of imminent flare is therefore expected to improve prognosis.

Objectives: In light of observed cases of de novo LN during belimumab treatment (1), we evaluated predictors of de novo renal flare occurrence in patients with systemic lupus erythematosus (SLE) and no prior history of renal disease undergoing standard therapy (ST) with or without add-on belimumab in clinical trial settings.

Methods: Data from five clinical trials of belimumab in SLE (BLISS-52 NCT00424476; BLISS-76 NCT00410384; BLISS-NEA NCT01345253; BLISS-SC NCT01484496; EMBRACE NCT01632241) were utilised. The study population comprised 1932 patients with a baseline renal British Isles Lupus Assessment Group (BILAG) score E. The current mainstay for the treatment of APS is anticoagulation with Vitamin K antagonists (VKAs). The primacy of Warfarin has been challenged by the introduction of direct oral anticoagulants (DOACs), stems from DOACs convenience, constant dosing, without the need for blood test monitoring and almost no drug interactions. However, the TRAPS study that compared Rivaroxaban to Warfarin treatment in APS patients was terminated prematurely due to higher incidence of thrombotic events in the Rivaroxaban group (1). Yet, all patients on the TRAPS trial were triple-aPL positive. Similar conclusions were demonstrated on the ASTRO study that compared Apixaban to Warfarin treatment (2). Because the risk profile of APS patients is heterogeneous, both clinically and serologically, it is difficult to conclude that treatment with DOACs is generally inferior to VKAs for all APS patients, for instance in the low-risk patient population.

Objectives: We assume that under real-life circumstances, VKAs narrow therapeutic range and the constant need for repeated INR checkups may change the above studies outcomes. Hereby, the aim of this study is to compare real-life outcomes of APS patients treated with DOACs to patients treated with Warfarin from the aspect of thrombotic events reoccurrence on one hand and bleeding events on the other hand. We also checked the outcomes specifically for different APS risk profile subgroups under different treatments with either Warfarin or DOACs.

Methods: 139 non obstetric APS patients from “Meir” medical center were followed up retrospectively for a mean period of 16 years, since diagnosis time until 31/12/2022. We gathered data on patients SLE status, aPL profile and type of thrombotic event at the time of diagnosis. We checked for thrombotic events reoccurrence and bleeding events (including their types) with respect to the specific treatment at the time of each event.

Results: Of 139 followed-up patients, we report a total of 217 thrombotic and 60 bleeding events. From the Warfarin treated group, 178 (82%) thrombotic events were recorded, 130 (74%) of them occurred in the high risk serological profile patients. From the DOACs treated group, 59 (16%) thrombotic event were recorded, 23 (39%) of them occurred in the high risk serological profile patients. 59 (98%) bleeding events were recorded in the Warfarin treated group, 46 (82%) among the high risk profile group. only one bleeding event was recorded in the DOACs group.

Conclusion: According to our single center data gathered retrospectively form a follow up of real- life APS patient’s treatment, Warfarin vs DOACs, we found higher incidence of thrombotic events (82%) in the Warfarin group compared to the DOACs group (59%). High risk profile patients had a higher thrombotic incidence in both groups. Moreover, patients taking Warfarin had a dramatically higher incidence of bleeding events comparing to DOACs (98% vs 0.01% respectively). These findings may raise the differences between real-life and controlled researches and may challenge the superiority of Warfarin. More researches are needed in order to answer this question.

Vasculitis - small vessel vasculitis

**POST155**

**COMPARISON OF THE ACR/EULAR 2022 CLASSIFICATION CRITERIA AND THE EMEA (THE EUROPEAN MEDICINES AGENCY) ALGORITHM IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV)**

**Keywords:** Validation, Vasculitis

Y Imai1, Y. Ota1, K. Matsutomo2, M. Akiyama1, K. Suzuki1, Y. Kaneko1, 1Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

**Background:** The anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitides (AAVs) are a group of disorders involving systemic, small- vessel vasculitis. The diseases include granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA). The diagnosis of vasculitis is challenging, due to the heterogeneous nature of these diseases. In 2022, ACR/EULAR proposed new internationally standardized classification criteria for AAV (ANCA-associated vasculitides). However, the performance of the new classification criteria have not been fully verified.

**Objectives:** To clarify the characteristics of the ACR/EULAR 2022 classification criteria (the 2022 criteria) in patients with AAV, by comparing those of the 2022 criteria with the existing European Medicines Agency (EMEA) algorithm.

**Methods:** All consecutive patients who had been newly diagnosed with AAV in Keio University Hospital between March 2012 and May 2022 were retrospectively reviewed. We reclassified them according to the EMEA algorithm and the 2022 criteria and identified their difference. We also analysed their clinical characteristics statistically.

**Results:** We included 114 patients in the analysis. The mean age at diagnosis of AAV was 67.2 ± 14.3, and 70 patients (61.4%) were female. According to the EMEA algorithm, the patients were classified as GPA in 21 patients, GPA in 43, MPA in 29, and unclassifiable in 21, while according to the 2022 criteria, they were classified as EGPA in 24, GPA in 13, MPA in 62. EGPA-MPA overlap in 1, GPA-MPA overlap in 6, and unclassifiable in 8. All 21 EGPA patients with the EMEA algorithm met the EGPA-2022 criteria. Forty three GPA patients with the EMEA were classified as EGPA in 1, GPA in 11, MPA in 24, GPA-MPA overlap in 6, and unclassifiable in 1 with the 2022 criteria. Patients who were classified as GPA according to both criteria were significantly younger (53.0 ± 18.6 vs 74.5 ± 9.9 years old, respectively, P=0.003), female dominant (54.5% vs 20.8%, P=0.056), cPRA-ANCA positive (90.9% vs 0%, P=0.001), had frequent epistaxis (45.5% vs 0%, P=0.001), and less with interstitial lung disease (9.1% vs 58.3%, P=0.007) compared to those who were reclassified from GPA to MPA with 2022 criteria. Among the 29 MPA patients with EMEA, 26 patients also met the MPA classification criteria with 2022 criteria, while among the 21 unclassifiable patients with EMEA, 12 patients were classified as MPA. Patients who were reclassified from unclassifiable to MPA with 2022 criteria were significantly older (75.2 ± 8.7 vs 57.7 ± 5.9 years old, P=0.002), had more p/MPO-ANCA (100% vs 11.1%, P=0.001), fewer ENT lesions (0% vs 55.6%, P=0.003), and tended to have more interstitial lung disease (75.0% vs 33.3%, P=0.056) than 9 patients who did not meet the MPA-2022 criteria. During the average observation period of 3.95 ± 2.91 years, 16 patients deceased. The 16 deceased patients were classified as GPA in 7, MPA in 6, and unclassifiable in 3 with the EMEA algorithm, while they were classified as MPA in 14, GPA-MPA overlap in 1, and unclassifiable in 1 with the 2022 criteria. Overall survival was not significantly different with the EMEA algorithm (P=0.21), whereas it was significantly shorter in patients with MPA according to the 2022 criteria (P=0.023).

**Conclusion:** Among the cases classified as GPA or unclassifiable by the EMEA algorithm, older cases with a high rate of p/MPO-ANCA and interstitial lung disease reclassified as MPA by the 2022 criteria were detected. The 2022 criteria is also useful for prognostic prediction compared to the EMEA algorithm.

**GLUCOCORTICOID-SPARING EFFECT OF MEPOLIZUMAB: REAL LIFE EXPERIENCE IN A MONOCENTRIC COHORT OF PATIENTS AFFECTED BY EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS**

**Keywords:** Real-world evidence, Vasculitis, Tapering

S. Bertocchi1,2, F. Regola1,2, M. Tagletti1, F. Franceschini1,2, P. Tonioli1,1,2, T. Spedali Civil, Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 1University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy

**Background:** Oral glucocorticoids (GC) are the mainstay of treatment for eosinophilic granulomatosis with polyangiitis (EGPA) but chronic exposure to GC is associated with serious comorbidities. Mepolizumab (MEPO) demonstrated to be an efficacious treatment for EGPA in the randomized controlled MIRRA trial [1]. ACR guidelines suggest treating non-severe EGPA with MEPO associated with GC as first choice and adding MEPO in non-severe relapses occurred while receiving other immunosuppressors. There are insufficient data to support dosages and duration of GC treatment during MEPO treatment, although guidelines suggest prescribing the minimum effective dose to minimize GC toxicity [2].

**Objectives:** The aim of the study was to evaluate the GC-sparing effect of MEPO in our cohort of patients affected by EGPA.

**Methods:** We enrolled 26 patients affected by EGPA according to MIRRA criteria and/or ACR criteria [1][3]. We compared cumulative GC dosage prescribed in the 6 months before beginning treatment with MEPO to the cumulative dosage prescribed in the 6 months after starting MEPO. We also analyse MEPO efficacy comparing median number of asthma attacks, BVAS and VDI.

**Results:** Twenty-six patients (M/F 16/10) affected by EGPA were diagnosed at a median age of 57 years (IQR 47-65) and started therapy with MEPO after a median disease duration of 6 (1.5-10) years. Overall clinical features of patients before MEPO starting, at MEPO starting (T0) and after 6 months of MEPO (T6) are described in Table 1a. At MEPO starting (T0), 24/26 (92.3%) were treated with GC and 13/26 (50%) were on treatment with other immunosuppressants (1 cyclosporine, 2 methotrexate, 3 mycophenolate, 7 azathioprine). The cumulative GC dosage administered to patients in the six months after MEPO starting was significant lower if compared with dosage in the prior six months. After MEPO starting, there was also a significant reduction of asthmatic flares number and BVAS score, with no increasing in VDI score (Table 1b and 1c). Eleven patients were treated with MEPO 300mg monthly, and 15 with 100mg monthly, with no statistically significant differences in clinical response.

AGE, FRAILTY, AND OUTCOMES IN OLDER ADULTS WITH ANCA-ASSOCIATED VASCULITIS

Keywords: Epidemiology, Real-world evidence, Vasculitis

S. E. Sattil1, X. Fu2,3, C. Cook2,3, S. Srivatsan2,3, Y. Zhang2,3, Z. Wallace2,3
1University of Pittsburgh, Division of Rheumatology and Clinical Investigation, Pittsburgh, United States of America; 2Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; 3Massachusetts General Hospital, Clinical Epidemiology Program, Morgan Institute, Boston, United States of America

Background: Older adults with ANCA-associated vasculitis (AAV) have differences in clinical presentation, as well as increased mortality and risk of infections, when compared to younger adults. Despite a high incidence of AAV in older adults, these individuals are underrepresented in clinical trials. Frailty, a geriatric syndrome associated with increased morbidity and mortality, has not been adequately studied in older adults with AAV. Better characterization of outcomes and risk factors in these patients is needed to inform treatment.

Objectives: To compare the risks of and factors associated with early (within 2 years) end-stage renal disease (ESRD), severe infection, and death in adults with a new diagnosis of AAV who are ≥ 75 years old vs 65-74 years old.

Methods: Patients ≥ 65 years were included from the 2002-2019 Mass General Brigham AAV cohort, a consecutive inception cohort. EGPA patients were excluded. Covariates including demographics, disease characteristics, and comorbidities (Charlson comorbidity index) were assessed at baseline. Disease activity at time of diagnosis was assessed using the Birmingham Vasculitis Activity Score (BVAS/WG). Frailty was measured at baseline using a claims frailty index, and pre-established cut-offs were utilized to define degrees of frailty (robust, pre-frail, mildly frail, and moderately/severely frail).[1] Death and ESRD were ascertained from linkage to national registries and/or medical records. Severe infections were identified utilizing inpatient data and/or death certificates. The cumulative incidence of death, ESRD and severe infections within 2 years were estimated. In univariate analyses, we assessed factors associated with outcomes within 2 years.

Results: 298 individuals were included. Most patients were female (61%), white (86%), MPO-ANCA+ (80%), and had renal involvement (72%). Patients ≥ 75 years old (n=156) had a median age of 81 years, while median age was 69 years in the 65-74 years group. The cumulative incidence at 2 years of the composite outcome of ESRD/death (23.1% [95% CI 16.5, 29.7]) vs 5.6% [95% CI 1.8, 13.3] in the 65-74 years old (n=440) was 4.42 (2.05, 9.51); frailty was not (HR 2.71, 95% CI 0.63, 11.72) (Table 1). In contrast, frailty with an increased risk of ESRD/death (hazard ratio (HR) 4.42, 95% CI 2.05-9.51) was a very strong risk factor for severe infection. These findings highlight the need for innovative considerations beyond age when assessing outcome risks in AAV.

RITUXIMAB VS. COMBINATION OF RITUXIMAB AND CYCLOPHOSPHAMIDE INDUCTION THERAPY FOR ANCA-ASSOCIATED VASCULITIS: A RETROSPECTIVE STUDY

Keywords: Real-world evidence, Quality of care, Vasculitis

K. Von Allwörden1, S. Klapa2, S. C. Werth3, A. Müller1, G. Riemenkasten1, M. Nitschke2, D. Thaçi3, P. Lamprecht1. 1Universität zu Lübeck, Rheumatologie, Lübeck, Germany; 2Universität zu Lübeck, Nephrologie, Lübeck, Germany; 3Universität zu Lübeck, Entzündungsmedizin, Lübeck, Germany

Background: In ANCA-associated vasculitis (AAV), the use of rituximab (RTX) according to the RAVE trial [1] or RTX in combination with cyclophosphamide (CYC) according to the RITUXVAS trial [2] showed noninferiority to CYC for the induction of remission. However, there is a lack of comparative real-world data between both therapy regimens.

Objectives: To compare the effectiveness of RTX with combined RTX/CYC for remission induction in AAV.

Methods: In this comparative effectiveness retrospective monocentric study, data of 166 patients with AAV (granulomatosis with polyangiitis [GPA] n=97; microscopic polyangiitis [MPA], n=69) were analyzed. Patients were treated first-line with RTX, RTX/CYC, or CYC between January 2012 and November 2022. The primary outcome was the remission rate at 24 months. Clinical data (BVAS, therapy, and serologic markers [creatinine, protein excretion, CRP, immunoglobulin levels]) were assessed at baseline and every 6 months up to 24 months.

Results: Of the 166 patients, 81 received first-line RTX (RAVE), 23 RTX/CYC (RITUXVAS), and 62 CYC according to CYCLOPS [3]. At baseline, there was no difference between RAVE and RITUXVAS treatment groups with respect to disease activity (BVAS; RAVE vs RITUXVAS: 12.07±6.69 vs 16.12±9.85, P=0.2083). In AAV, treatment according to RAVE and RITUXVAS was not inferior to treatment according to CYCLOPS (Figure 1). Moreover, RTX was not inferior to RTX/CYC (HR 0.61, P=0.1356, Figure 1). Interestingly, subgroup analysis showed RAVE was slightly superior to RITUXVAS in GPA (HR: 0.48, P=0.0408, Figure 1).

Conclusion: In AAV, RTX and the combination of RTX/CYC were not inferior to CYC, the combination of RTX and CYC was not superior to RTX alone.

EVALUATION OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR GPA AND MPA IN A EUROPEAN ANCA-ASSOCIATED VASCULITIS (AAV) COHORT

Keywords: Vasculitis, Validation

S. Krämer1, T. Rauen1, K. Pruin1, T. Anslinger2, M. Busch2, T. Schmitt2, R. Berger2, S. Mosberger2, T. Neumann2. 1RWTH, University Hospital Aachen, Department of Nephrology and Rheumatology, Aachen, Germany; 2University Hospital Jena, Friedrich-Schiller University, Department of Internal Medicine, III, Jena, Germany; 3Municipal Hospital Ludwigshafen, Department of Internal Medicine A, Nephrology and Rheumatology, Ludwigshafen, Germany; 4Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland

Background: In 2022, the ACR and the EULAR proposed new classification criteria for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) based on numerical item scoring for different manifestations in ANCA-associated vasculitis (AAV). Recently, a low concordance rate of only 73% in comparison with the 2012 revised International Chapel Hill Consensus Conference Nomenclature and the 2007 European Medicines Agency (EMA) algorithm [1] was reported in a Korean cohort of 65 GPA patients.

Objectives: We performed a retrospective classification according to the new 2022 classification criteria of patients from our multi-centric AAV cohort, using a computational algorithm that involved existing clinical, laboratory and histological data performed well to categorize 98% of all cases.

Results: The final dataset included 305 cases, 294 (96.4%) of Caucasian ethnicity, 161 males (52.8%), median age 61 years (IQR 50-70). Based on the 2022 ACR/EULAR criteria, 299 (98%) cases could be unambiguously categorized, 180 patients were classified as GPA and 119 as MPA (Table 1). Positive concordance, i.e. patients matching the novel classification criteria and clinical diagnosis, was higher in GPA than in GPA patients (98.8 vs. 90.8%). By contrast, negative concordance, i.e. proportion of cases negative for both clinical and novel classification-based diagnosis, was higher in GPA (97.3 vs. 84.1%). Twenty-seven cases of renal limited disease were mostly reclassified as MPA (92%).

POS1164

WITHDRAWN
**Background:** ANCA-associated vasculitis (AAV) carries excessive morbidity and mortality owing to the delay in diagnosis and limited prognostication. Identifying clinically useful biomarkers of disease activity that facilitate accurate prognostication would help personalize management decisions. Biomarkers used in day-to-day practice include PR3- or MPO-ANCA, CRP, and ESR, but these poorly predict future disease activity. Few studies have examined a limited number of circulating proteins as biomarkers, including BCA-1, MMP-3, TIMP-1[1-4]. We previously leveraged a high-throughput, unbiased approach to investigate 92 potential biomarkers for disease prognostication in AAV patients and identified 5 potential biomarkers.

**Objectives:** To further investigate the association of 5 novel protein biomarkers with AAV disease activity.

**Methods:** Serum samples from patients in the Mass General Brigham (MGB) AAV cohort were retrieved from the MGB Biobank following IRB approval. We chose a random 78 subjects who had AAV. We classified disease activity as “Active” or “Remission” at sample collection. The O-link high-throughput proteomic assay was used to measure the levels of 5 proteins of interest (MCP3, TNFSF-14, FIT3L, and SCF). For analysis, protein levels were first normalized. We compared protein levels in active disease vs remission. ESR, CRP, white blood cell (WBC) count and platelet levels were extracted for comparison. Using the mean value of each potential biomarker in the cohort as cut-off values, we determined the odds ratio (OR) and the area under the receiver operating curve (AUC) of the association of elevated biomarkers with active disease.

**Results:** Of n=78, the mean age was 57.3 +/- 17.6, 55% were female, and 28% had active disease at sample collection. When examining the outcome of active disease vs remission, abnormal levels of OSM, TNF-SF-14, FIT3L, and SCF differentiated disease states: OR of 5.10 (p=0.005), 3.71 (p=0.017), 0.13 (p=0.001), and 0.34 (p=0.040), respectively. AUC analysis indicated that TNF-SF-14 (0.731, CI 0.601-0.862), OSM (0.745, CI 0.622-0.867), and FIT3L (0.757, CI 0.644-0.871) were more strongly associated with active disease than other biomarkers, including WBC (0.703, CI 0.566-0.840), platelets (0.680, CI 0.551-0.809), CRP (0.549, CI 0.376-0.721), and ESR (0.547, CI 0.372-0.722).

**Conclusion:** Using a high-throughput, unbiased proteomics approach, we further investigated 5 novel candidate markers differentiating active AAV disease from remission. These proteins likely reflect different states of immune activation during active disease and outperform conventional inflammatory markers (e.g., CRP, ESR) as well as WBC and platelets. Our study has certain limitations, including sample size, a cross-sectional study design, and requires validation across diverse, longitudinal cohorts. The potential for biomarkers that accurately identify those individuals in remission compared to active disease may facilitate tailored, personalized therapeutic intervention, which avoids unnecessary exposure to the toxic side effects of immunomodulatory agents.

**IDENTIFICATION OF KEY GENES AND IMBALANCE OF IMMUNE CELL INFRINGEMENT IN IMMUNOGLOBULIN A-ASSOCIATED VASCULITIS NEPHRITIS BY INTEGRATED BIOINFORMATIC ANALYSIS**

**Keywords:** Cell biology, Vasculitis, Genetics/epigenetics

X. MA1, X. Jia1, H. Zhu1, R. Wang1, Y. Shan1. 1The First Hospital of China Medical University, Department of Pediatrics, Shenyang, China; 2University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

**Background:** Immunoglobulin A associated vasculitis (IgAV), also known as Henoch-Schonlein purpura, is a common systemic vascular inflammatory disease that chiefly manifests as skin purpura, arthritis, abdominal pain, gastrointestinal bleeding, and kidney involvement [1]. It is characterized by immunoglobulin A dominant immune deposition in small blood vessels, and the excessive production of various inflammatory molecules [2]. Although the etiology and pathogenesis of IgAV are not fully understood, there is increasing evidence that infection, genetic susceptibility, and immune response disorders are closely related to the development and progression of IgAV [3,4]. Meanwhile, abnormal expression of immune factors and imbalance of immune cell differentiation in general circulation may play crucial roles in the pathogenesis of IgAV [5]. Therefore, it is necessary to identify key pathways and immune cells in vasculitis, and to assess the significance of the immune microenvironment in the pathogenesis of IgAV.

**Objectives:** This study was conducted to identify differentially expressed genes (DEGs) and find dysregulated immune cell types in IgAV to find the underlying pathogenesis for IgAV to the effective prediction of therapeutic targets in the future.

**Methods:** GSE102114 datasets were obtained from the Gene Expression Omnibus (GEO) database to identify DEGs. Then, the protein-protein interaction (PPI) network of the DEGs was constructed using the STRING database. And key hub genes were identified by cytoHubba plug-in, performed functional enrichment analyses and followed by verification using PCR based on patient samples. Finally, the abundance of 24 immune cells were detected by Immune Cell Abundance Identifier (ImmuCellIA) to estimate the proportions and dysregulation of immune cell types within IgAV.

**Results:** A total of 4200 DEGs were screened in IgAV patients compared to Health Donor, including 2044 upregulated and 2166 downregulated genes. Of the top 10 hub genes from PPI network, STAT1, TLR4, PTEN, UBB, HSPA9, ATP5B, UBA52, and CDC42 were verified significantly upregulated in more patients. Enrichment analyses indicated that hub genes were primarily enriched in Toll-like receptor (TLR) signaling pathway, nucleotide oligomerization domain (NOD)-like receptor signaling pathway, and Th17 signaling pathways. Moreover, we found a diversity of immune cells in IgAV, consisting mainly of T cells. Finally, this study suggests that the overdifferentiation of Th2 cells, Th17 cells and Tfh cells may be involved in the occurrence and development of IgAV.

**Conclusion:** We screened out the key genes, pathways and maladjusted immune cells and associated with the pathogenesis of IgAV. The unique characteristics of IgAV-infiltrating immune cell subsets were confirmed, providing new insights for future molecular targeted therapy and a direction for immunological research on IgAV.

**SHORT-TERM OUTCOME OF ADULTS WITH IGA VASCULITIS – A SINGLE CENTER EXPERIENCE**

**Keywords:** Vasculitis, Prognostic factors

A. Hoeværj, J. Østrovskni, M. Tomsic, Z. Rutar. 1 University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia

**Background:** Follow-up data on IgA vasculitis (IgAV) in adults are scarce compared to paediatric population.

**Objectives:** The aim of our study was to investigate the short-term outcome in a well-defined adult IgAV cohort.

**Methods:** We analyzed medical records of historically proven adult IgAV cases diagnosed between January 2010 and July 2022, and followed at our rheumatology center for more than 3 months. The frequency and type of relapses were studied. In addition the information on renal function (creatinine, estimated glomerular filtration rate (eGFR)) and urine analysis was recorded. Persistent abnormal urinanalysis was defined as persistent haematuria (>10x10^6 red blood cells/L) and/or daily proteinuria >300 mg. A significant worsening of renal function during follow-up was defined as eGFR decline >20% from baseline. Risk factors for relapsing IgAV and persistent abnormal urinanalysis were studied using Cox regression analysis.

**Results:** We identified 362 IgAV patients (59.4% males, median (IQR) age 60.4 (26.4; 76.2) years). Four patients died during the acute IgAV. Of the remaining patients, 76 (72.3%) were followed for a median (IQR) range 24.1 (12.5, 55.2; range 3.0 to 146.1) months, while 93 patients had either a follow-up time less than 3 months or were lost to follow up. Of 265 patients 38.9%, 29.8% and 44.5% had at baseline arterial, gastrointestinal, and renal involvement, respectively, and 28.3% had skin limited IgAV. One hundred and eighty-nine (71.3%) patients received at baseline systemic glucocorticoid, and 32 (12.1%) additional immunomodulatory therapy. One patient transiently required haemodialysis. During the follow-up period 42 (15.8%) patients relapsed. Table 1 shows the frequency and type of relapses. As factors associated with relapses emerged age (HR 0.97 (95% CI 0.95; 0.99)), and the use of systemic glucocorticoid at initial presentation (HR 2.37 (95% CI 1.98; 2.85), articular involvement (HR 4.02 (95% CI 0.25; 0.70)) and proteinuria >1g. As factors associated with persistent abnormal urinanalysis emerged heart failure as comorbidity (HR 2.28 (95% CI 1.20; 4.32), articular involvement (HR 2.93 (95% CI 1.65; 5.20)) and proteinuria >1g. As factors associated with persistent abnormal urinanalysis emerged heart failure as comorbidity (HR 2.28 (95% CI 1.20; 4.32), articular involvement (HR 2.93 (95% CI 1.65; 5.20)) and proteinuria >1g.

**Conclusion:** Fifteen percent of our adults had relapsing IgAV course, with skin relapses being the predominant relapse type. Younger patients with symptomatically managed IgAV were more prone to relapse. Persistent abnormal urinanalysis was recorded in a quarter of patients. Concurrent heart failure had an impact on the persistent renal pathology in adult IgAV.

**NOMOGRAM FOR IDENTIFYING THE HIGH-RISK PATIENTS OF ORGAN INVOLVEMENT IN EARLY-STAGE ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS**

**Keywords:** Vasculitis

R. Wu1, R. Su2, C. Wang3. 1 The Second Hospital of Shanxi Medical University, The Department of Rheumatology, Taiyuan, China

**Background:** Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is characterized by small-vessel vasculitis and systemic autoimmune inflammatory response [1, 2]. Although AAV is rare, the condition of AAV is relatively easy to diagnose. The clinical manifestations of patients with AAV are different [3], ranging from mild non-specific symptoms to severe life-threatening organ involvement. Therefore, the clinical need to achieve accurate and quick identification for the high-risk groups of organ involvement in early-stage AAV remains strong.

**Objectives:** There is no study to identify the high-risk patients with organ involvement of early-stage AAV. We aimed to develop a model to identify those high-risk patients at an early stage of AAV.

**Methods:** The data of the 74 new-onset patients with AAV (61 of whom had definite organ involvement) was collected in our retrospective study. The predictor variables for organ involvement in AAV were assessed by the logistic regression analysis. We developed the risk stratification model by nomogram. And the model was validated by concordance index, calibration curve, and decision curve analysis.
Results: The logistic regression analysis showed that BVAS, IL-17 and Treg cells were the predictor variables for organ involvement in AAV (Figure 1). We constructed a nomogram model consisting of BVAS, Treg cells and IL-17 (Figure 2A). In the nomogram, the value of each predictor was assigned a certain number of points, and the sum of the points for each predictor corresponded to the risk of organ involvement in AAV. Then we evaluated the nomogram model. The calibration curve in 1000 bootstrap replications revealed a good predictive accuracy between the predicted probability and observed probability of the nomogram model with a Concordance index (C-index) of 0.957 (95% CI = 0.694–0.960) and bias-corrected C-index of 0.937 (Figure 2B). And the chi-squared of Hosmer–Lemeshow test was 0.37 (P = 0.83) indicating a good fitness of the model. Next, the receiver operating characteristic (ROC) curve of the model (Figure 2C) yielded the AUC of the curve was 0.9571 (95%CI =0.9124–1.000) showing it had a great ability for discriminating organ involvement in AAV. The decision curve analysis (DCA) showed a positive net benefit for patients with organ involvement (Figure 2D), which suggested that patients with organ involvement could benefit from interventions. And the clinical impact curve (Figure 2E) showed that the risk of organ involvement predicted by the nomogram model under threshold probability (red curve) was close to the actual value of organ involvement events under each threshold probability (blue curve).

Conclusion: The risk stratification nomogram model was effective to identify the high-risk patients of organ involvement in early-stage AAV, and it was validated with good discrimination, calibration as well as great application value in clinical.

RECOVERY AND LONG-TERM RENAL OUTCOME OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIS WHO ARE ON DIALYSIS AT PRESENTATION

Keywords: Vasculitis
Y. J. Lee1, S. M. Ahn1, S. Hong1, J. S. Oh2, C. K. Lee1, B. Yoo1, Y. G. Kim1. 1Asan Medical Center, Division of Rheumatology, Department of Internal medicine, Seoul, Korea, Rep. of (South Korea); 2Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)

Background: Renal involvement in ANCA-associated vasculitis (AAV) can lead to severe renal dysfunction requiring dialysis at the time of diagnosis. Studies have demonstrated that a significant proportion of patients could discontinue dialysis after treatment, with dialysis recovery-associated factors including kidney pathology such as proportion of normal glomeruli and extent of tubular atrophy or interstitial fibrosis. However, these works focused on short-term outcomes within 6–12 months after AAV diagnosis (1, 2). Research reporting if patients who discontinued dialysis resumed during long-term follow-up are lacking.

Objectives: We assessed the clinical and pathologic characteristics of patients with AAV dependent on dialysis at presentation and the long-term renal outcomes of those who recovered after dialysis.

Methods: This retrospective study analyzed the data of patients diagnosed with AAV who were on dialysis at baseline from July 2005 to May 2021 at a single tertiary center in Korea. Medical records, including renal function and dependence on dialysis, were obtained.

Results: We included 34 patients on dialysis at the time of AAV diagnosis in this study. The median age was 64.5 years, and 61.8% were female. Among all patients, 13 discontinued dialysis and 21 remained dialysis dependent. The proportions of normal glomeruli (p<0.001) and interstitial fibrosis (p=0.024) were significantly different between the two groups. The multivariable analysis revealed that the proportion of normal glomeruli tended to be associated with dialysis discontinuation (OR=1.34, 95% CI 0.88–1.27, p=0.068). Treatment modalities, including plasmapheresis, were not significantly associated with dialysis discontinuation. In the follow-up analysis of 13 patients who had discontinued dialysis for a median of 81 months, 12 did not resume dialysis, and their glomerular filtration rate values had significantly increased at follow-up compared with at dialysis cessation (37.5 [28.5–45.5] vs. 24.0 [18.5–30.0] mL/min/1.73 m², p<0.008).

Conclusion: Approximately 38% of AAV patients discontinued dialysis, and the recovered patients had improved renal function without dialysis. Thus, patients with AAV on dialysis should be considered for dialysis discontinuation and renal recovery, especially those with normal glomeruli in kidney pathology.

with other vasculitides. Various biomarkers are developed to predict outcome of AAV. Recently, a novel index, triglyceride (TG) glucose-body mass index (BMI) (TyG-BMI) was introduced to predict insulin resistance (IR), cardiovascular disease, cerebrovascular accidents in general population. Given that IR and its related diseases such as CVD and CVA are generally major risk factors for all-cause mortality in the general population, it could be assumed that TyG-BMI could be a robust predictor of all-cause mortality in AAV patients.

**Objectives:** This study aimed to investigated whether TyG-BMI and a new index using TyG-BMI (NITGB) could predict all-cause mortality in nonobese patients with AAV.

**Methods:** The medical records of 78 nonobese AAV patients (BMI < 23.0 kg/m²) for Asian) were retrospectively reviewed. TyG-BMI was calculated by the equation: Ln [(triglyceride x fasting glucose)/2] x BMI. To develop NITGB, we assigned a weight of 0.1 to each variable according to the slopes for independent variables with P-value < 0.1 in the multivariable Cox analysis.

**Results:** The median age was 54.3 years and five patients died. When nonobese AAV patients were divided into two groups based on TyG-BMI ≥ 187.74, those with TyG-BMI ≥ 187.74 exhibited a significantly higher risk for all-cause mortality than those without (RR 284.000). Since age (HR 1.324), Birmingham vasculitis activity score (BVAS; HR 1.12), and TyG-BMI ≥ 187.74 (HR 12.168) were independently associated with all-cause mortality, NITGB was developed as follow:

There were a significantly higher risk for all-cause mortality than those without (RR 284.000).

**Conclusion:** Both nonobese AAV patients with TyG-BMI ≥ 187.74 and those with NITGB ≥ 27.36 exhibited significantly cumulative rates of all-cause mortality than those without. NITGB along with TyG-BMI could predict all-cause mortality in nonobese AAV patients.

**REFERENCES:**

was 470.0%, 54.6%, 91.7%, 97.6% and 77.3%, respectively, whereas the mean (SD) total BODI score was 1.1 (1.7), 1.2 (1.7), 3.5 (2.4), 4.5 (2.6), and 1.9 (1.9). The prevalence of different BODI domains is reported in the Table 1. Significant differences were recorded in NA vs. EU and ME cohorts (Figure 1) (CA and AM not included in the statistical analysis for the small sample size). In multivariate analysis, the geographical area was independently associated (p < 0.001) with damage (NA vs. EU OR 11.3; ME vs. EU OR 1.5). Male gender (OR 1.5; p = 0.004), age (OR 1.03 per year; p = 0.002), disease duration (1.03 per year; p = 0.003), ocular (OR 2.8; p < 0.001), vascular (OR 5.3; p < 0.001), and neuropsychiatric (OR 5.8, P<0.001) involvement were also associated with BODI≤1.

Conclusion: A variable prevalence of organ damage was observed in BS patients from different World areas. Further research is needed to understand the cause underlying such geographic variability, as it may unveil biological, environmental, or health-system factors driving damage accrual in BS. The BODI effectively captures damage independently from the studied cohort’s geographical origin.

POS1173
LONG-TERM ANALYSIS OF RELAPSE RATES IN A EUROPEAN ANCA-ASSOCIATED VASCULITIS (AAV) COHORT FOR GPA AND MPA

Keywords: Registries, Vasculitis

Background: Therapeutic interventions for ANCA-associated vasculitides (AAV) dramatically changed over the last two decades. Especially the introduction of rituximab into the therapeutic portfolio significantly improved outcome data, whereby relapse rates in previous cohorts were mostly reported from only up to two-year periods.

Objectives: With the present study, we thought to retrospectively investigate the overall relapse rates in a large European AAV cohort.

Methods: Data of patients with newly diagnosed GPA and MPA (retrospectively classified on ACR/EULAR 2022 criteria) from four tertiary referral centers in Germany and Switzerland were collected between 2000 and 2021. Events were captured during routine out-patient visits and hospital admissions. A relapse was considered at the time of any increased vasculitis activity, i.e. therapeutic necessity to increase glucocorticoids ≥10 mg prednisolone per day. First relapse occurrence was analyzed as time-to-event analysis and number of cases for each group. Differences were compared by ANOVA- and X²-test, respectively.

Results: Our data set comprised a total of 338 patients, 46.2% women (mean age of 59.2±14.7 years). Of these, 203 cases (60.1%) were classified as GPA and 135 (39.9%) as MPA. At initial presentation, 74.9% of patients exhibited renal, 50.9% pulmonary and 35.2% ENT involvement. Over a median follow-up period of 58.7 months (IQR 29.4 to 101.7) we observed an overall relapse rate of 35.8% in the entire cohort and median time to first relapse was 32.6 months. GPA patients exhibited consistently higher relapse rates than those with MPA over the entire observational period.

Conclusion: In our European AAV cohort, we observed an overall relapse rate of 35.8% for both AAV entities with the first relapse occurring after a median of 32.6 months. GPA patients exhibited consistently higher relapse rates than those with MPA over the entire observational period. We propose that future analyzes of relapse rates should cover a minimum of three years to capture roughly half of all expected events.

POS1174
IMPACT OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA ON CLINICAL DIAGNOSIS OF ANTEINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) ASSOCIATED VASCULITIS

Keywords: Vasculitis, Real-world evidence

J. Van Leeuwen1, S. Hafemann1, Y. K. O. Teng1, J. Van Leeuwen1, S. Hafemann1, Y. K. O. Teng1. Leiden University Medical Center (LUMC), Nephrology Section - Internal Medicine Department, Leiden, Netherlands.

Background: In 2022 the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) presented new classification criteria for the three subsets of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV): granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and Eosinophilic Granulomatosis with Polyangiitis (EGPA) [1-3]. The purpose of this classification was to ensure homogeneous populations for clinical trials and research. These criteria were developed based on a population of patients with a high certainty of diagnosis [1-3]. As with any novel criteria, these can potentially lead to re-classification of AAV patients which can impact selection of patients in future studies.

Objectives: To assess the impact of the new 2022 ACR/EULAR classification criteria for GPA, MPA and EGPA on re-classification of clinical diagnoses of AAV patients.

Methods: An established cohort of 337 patients of AAV patients at a single center, academic hospital was used to screen patient and disease characteristics and clinical data at the time of diagnosis and matched to the novel 2022 ACR/EULAR classification criteria for GPA, MPA or EGPA. Patients with an unspecified AAV diagnosis and patients with no clinical data or only ANCA serology available for the time of diagnosis were excluded.

Results: Out of 337 patients, 86 patients with GPA experienced at least one relapse (42.4%) whereas in MPA only 35 (25.9%) patients relapsed (p<0.01). In addition, log-rank test revealed a significant difference in relapse over time (p<0.05, Figure 1). The median time to the first relapse did not differ significantly between GPA and MPA patients (GPA: 27.9 months, IQR 13.6 to 55.9, vs. MPA: 35.1 months, IQR 8.6 to 55.9, p=0.458).

Conclusion: In our African AAV cohort, we observed an overall relapse rate of 35.8% for both AAV entities with the first relapse occurring after a median of 32.6 months. GPA patients exhibited consistently higher relapse rates than those with MPA over the entire observational period. We propose that future analyzes of relapse rates should cover a minimum of three years to capture roughly half of all expected events.
Results: In total 249 patients, 160 (64%) and 89 (36%) females, with a median age of 66 (range 12-96) and a AAV diagnosis between 1983 to 2022, were included. 179 patients had a clinical diagnosis of GPA, 43 of MPA and 27 of EGPA. Of the 179 GPA patients, 155 (87%) met the classification criteria for GPA, 15 (8%) for MPA and 10 (6%) remained unclassified. One patient could be classified as both GPA and MPA. Of the 43 MPA patients, 33 (77%) classified as MPA, 8 (19%) as GPA and 3 (7%) patients remained unclassified. Again, one patient could be classified as GPA and MPA. Only 14 of 27 (52%) EGPA patients met the classification criteria for EGPA. Those (11%) EGPA patients classified as GPA, 4 (15%) as MPA and 6 (22%) remained unclassified. These results show a lower sensitivity than observed in the development study (87 vs 93% for GPA, 78 vs 93% for MPA and 52 vs 85% for EGPA).[1-3] When analysing our cohort based on ANCA specificity, from 67 MPO positive patients, 50 (75%) would classify as GPA, 9 (13%) as MPA and 4 (6%) as EGPA. Clinical diagnosis was MPA in only 40 (60%) of patients and GPA in 18 (27%) patients and EGPA in 9 (13%) patients. From 145 PR3 positive patients, 141 (97%) would classify as GPA, none as MPA and 1 (1%) as EGPA, compared to 140 (97%) clinical diagnosis of GPA, 1 (1%) of MPA and 4 (3%) of EGPA.

Conclusion: When comparing the EULAR/ACR classification criteria to real-life clinical diagnosis, 13% of GPA patients, 23% MPA patients and 48% of EGPA patients would not meet the criteria for the corresponding classification. Moreover, because the presence of ANCA auto-antibodies is highly weighted, the percentage of MPO positive GPA patients is diminished. We demonstrate using these new criteria will impact selection of patients in future studies, especially for EGPA studies.

POS1175 ANTI-IL5 THERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: DOSAGE, EFFICACY AND OUTCOME IN A LARGE COHORT OF PATIENTS IN REAL LIFE (REVAS STUDY)

Keywords: Targeted synthetic drugs, Descriptive studies, Vasculitis

1 Vall d’Hebron University Hospital, Internal Medicine, Barcelona, Spain; 2 La Paz University Hospital, Internal Medicine, Madrid, Spain; 3 San Cecilio University Hospital, Internal Medicine, Granada, Spain; 4 Cabueñes Hospital, Internal Medicine, Gijón, Spain; 5 Clinic University Hospital Santiago Compostela, Internal Medicine, Santiago de Compostela, Spain; 6 Bellvitge University, Internal Medicine, Barcelona, Spain; 7 Gregorio Marañon University Hospital, Internal Medicine, Madrid, Spain

Background: Eosinophilic granulomatosis with polymyagiitis (EGPA), formerly Churg-Strauss syndrome, is a rare type of anti-neutrophil cytoplasm antibody-associated vasculitis, associated with asthma, nasal poliosis and sinusinflons, in which eosinophils play a key role. Eosinophil targeted therapies alone or associated to conventional treatment with corticosteroids and immunosuppressant drugs may be useful in its management. DAA treatment for severe asthma manifestations often presents difficulties to treat.

Objectives: To describe the indications, dosage, efficacy and safety of, eosinophils targeted therapies in patients with EGPA in a real practice.

Methods: Retrospective study evaluating all patients with EGPA included at REVAS Registry, treated with anti-IL5 therapy, in order to assess the effectiveness and safety of this therapy. Treatment response was evaluated from 3 months to the censoring data. Complete response (CR) was defined as the absence of asthma and/or sinusonal exacerbations with a prednisone dosage of ≤5mg/day, and partial response (PR) if the prednisone dosage was 25mg/day. Statistical analysis was performed using SPSS 21 package.

Results: Fifty patients (median age 47 years) were evaluated. Forty-five (90%) patients received mepolizumab (38 patients 100mg every 4 weeks and 7 patients 300mg every 4 weeks) for a mean period of 31 (1-68) months; 4 (8%) received benralizumab (30mg every 4 weeks) for a mean of 33 (7-42) months, and 3 (6%) received reslizumab (n=3, 6%) for a mean period of 54,3 (43-67) month. Anti-IL5 therapy was indicated for severe steroid-dependent asthma (94%) and/or persistent sinusonal involvement (80%). 11 (22%) patients also had symptoms of active vasculitis. 5 (10%) patients had monocrotaline. 2 patients cutaneous lesions, 1 orbital pseudotumor. ANCA were positive in 27 (54%) cases with MPO specificity. All patients were receiving corticosteroids at the time of anti-IL5 therapy beginning, with a mean dosage of 11,5mg/day. A total of 11 (22%) patients had previously received omalizumab, that was changed to mepolizumab in 9 cases, reslizumab in 1 and benralizumab in another, due to PR (n=5) or recurrence of asthma and/or sinusinflons (n=6) after a long period of treatment (70.5 months). Anti-IL5 therapy was given concomitantly to AZA in 7 cases, MTX in 3, and RTX in 2. 38 (84,4%) patients treated with mepolizumab achieved a CR after 6-18 months of treatment.

The median dosage of prednisone 6 months after mepolizumab, benralizumab and reslizumab initiation was 6 (5-15) mg/day, 5.3 (2.5-10) mg/day, and 3.3 (0-5) mg/day, respectively. The median dosage of prednisone 12 months after mepolizumab, benralizumab and reslizumab initiation was 6 (5-15) mg/day, 3.1 (0-5) mg/day, and 2.5 (0-5) mg/day, respectively. The median number of exacerbations decreased from 2.5 over the 6 months previous to therapy beginning to 1 in the following 12 months. CS were stopped in 12 (24%) patients. All 3 drugs were safe and well tolerated. During the follow-up period, three patients experienced a major relapse of the disease, and were successfully treated with RTX in conjunction with mepolizumab, with no serious adverse events. Mepolizumab dosage was reduced to 100mg every 6 months in 50% of cases. In one case mepolizumab was changed by benralizumab due to PR.

Conclusion: Mepolizumab at both 100mg every 4 weeks and 300mg every 4 weeks is effective for the treatment of EGPA. Both doses should be compared in the setting of a controlled trial. Benralizumab and reslizumab are also effective. Sequential therapy with anti-IL5 drugs and rituximab was safe and effective in achieving remission in patients with a major relapse of the disease.

DOI: 10.1136/annrheumdis-2023-eular.5344
Methods: Between 2007 and 2018, we examined the hospitalization records of AAV patients from 13 Italian hospitals. Hospitalization dates, features, length of stay, primary discharge diagnoses and patient data were abstracted from charts. Age and sex-standardized hospitalization rates (SHR) were calculated by an indirect method, per year and for the study period, using the 2007–2018 hospitalization data provided by the Italian Ministry of Health. Multivariable and survival models were used to explore associations between these outcomes, clinical parameters at diagnosis, and pre-existing comorbidities.

Results: A total of 610 hospitalizations occurred in 635 patients with AAV (19.4% microscopic polyangiitis, MPA; 34.8% granulomatosis with polyangiitis, GPA; 46.0% eosinophilic GPA, EGPA) during a 12-year observation; in 19.6% for life-threatening conditions and leading to death in 2.3%. The median time to first hospitalization was 504 days (25-75% IQR, 95-1497), and the median hospitalization length was 8 days (25-75% IQR, 8-14). The 2018 SHR (95%CI) was 1.14 (0.91, 1.43) for all AAV combined, 1.13 (0.68, 1.76) for MPA, 1.48 (1.02, 2.08) for GPA, and 0.90 (0.60, 1.31) for EGPA. These rates tended to a gradual increase from 2007 to 2018 in the whole AAV cohort of patients and in every disease subset (Figure 1A). The main causes of hospitalization in patients with AAV were infectious diseases (18.7%), followed by major relapse and diagnostic re-evaluation (17.2% each), and cardiovascular diseases (10.8%). Among those due to infections, the main site was the respiratory system (44.6%), followed by urinary tract (9.6%) and sepsis (6.3%). Among AAV patients hospitalized during follow-up (47.1%), 55.5% had only 1 hospitalization, 18.7% had 2, and 25.6% had 3 or more hospitalizations. Patients with a diagnosis of GPA or MPA (versus EGPA), higher vasculitis activity (assessed by BVAS), ANCA positivity at diagnosis, and hospitalization at diagnosis (all p<0.001), more pre-existing comorbidities and older age (both p<0.05), were more likely to be hospitalized during follow-up (Figure 1B).

Conclusion: Patients with AAV have a significant burden of hospitalization during the disease course. Approximately half of the patients is hospitalized during follow-up, with infections, relapses and cardiovascular diseases as the main causes of hospitalizations. Our findings showed the existence of risk profiles of patients more likely to be hospitalized, requiring more active vigilance.

POS1177 ROLE OF INTRATHecal PRODUCTION OF IL6 IN THE PATHOGENESIS OF CHRONIC PROGRESSIVE NEURO-BEHÇET’S DISEASE

Keywords: Cytokines and chemokines, Behcet’s disease

S. Hirohata1,2, H. Kikuchi1. 1Nobuhara Hospital, Rheumatology, Tatsuno, Japan; 2Tokyo University School of Medicine, Internal Medicine, Tokyo, Japan

Background: Behçet’s disease (BD) is characterized by recurrent attacks of aphthous stomatitis, uveitis, genital ulcers, and skin lesions, including folliculitis, erythema nodosum like lesions, and superficial thrombophlebitis of the central nervous system (CNS). Central nervous system involvement is one of the most frequent complications in BD and is called neuro-Behçet’s disease (NB). There has been accumulating evidence that NB can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical courses as well as in responses to corticosteroid treatment. Thus, ANB responds well to corticosteroids and usually runs a self-limiting course. By contrast, CPNB is characterized by intractable neuro-behavioral changes and cerebellar ataxia, which progress in spite of high doses of corticosteroids or immunosuppressive drugs, including azathioprine or cyclophosphamide.

Objectives: Previous studies have demonstrated that cerebrospinal fluid (CSF) IL-6 was elevated in patients with CPNB. However, little is known as to the mechanism of the elevation of CSF IL-6 in the pathogenesis of CPNB.

Methods: Paired serum and cerebrospinal fluid (CSF) samples were obtained from 19 patients with CPNB when they presented active neuropsychiatric manifestations and from 19 control patients with non-inflammatory neurological diseases. Among the 19 patients with CPNB, 5 patients received treatment with infliximab and followed up thereafter. The levels of albumin and IL-6 in CSF and sera were measured by ELISA. Blood-brain barrier (BBB) function was evaluated by Q albumin (CSF/serum albumin quotient x 1,000). The intrathecal production of IL-6 was evaluated by CSF IL-6 indices ([CSF IL-6 x serum albumin]/[serum IL-6 x CSF albumin]).

Results: Serum IL-6 and CSF IL-6 were significantly higher in 19 patients with CPNB compared with control patients with non-inflammatory neurological diseases. Among the 19 CPNB patients, serum IL-6 levels were not significantly correlated with CSF IL-6 levels (r=0.0938). As for 5 patients with CPNB treated with infliximab, all of CSF IL-6, serum IL-6, Q albumin and CSF IL-6 indices were significantly elevated compared with control patients with non-inflammatory neurological diseases. Treatment of the 5 patients with infliximab dramatically decreased CSF IL-6 in the next day, but neither serum IL-6 nor Q albumin (Figure 1). Of note, CSF IL-6 indices were dramatically decreased on the next day of treatment with infliximab in the 5 patients with CPNB (Figure 1).

Figure 1. Age- and sex-SHR by year for patients with AAV, MPA, GPA and EGPA during 2007-2018 (A). Kaplan-Meier Plots of the probability of hospitalization after AAV diagnosis (B).
Methods: Using a modified precipitation technique in hypo-ionic medium, we aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulins or show only trace amounts which cannot be characterized for composition.

Background: A considerable number of patients with high clinical suspicion for cryoglobulinaemic vasculitis either show negative results for the detection of cryoglobulins or show only trace amounts which cannot be characterized for composition.

Objectives: We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinemia). A considerable number of these patients had type III cryoglobulins in patients with cryoglobulinemia the histologic features of glomerulonephritis (also examined by electron microscopy) resembled those of mixed cryoglobulinemia-associated glomerulonephritis.

Conclusion: In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinaemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

POS1178 IDENTIFYING THE NEW DISORDER “IDIOPATHIC HYPOCRYOGLOBULINAEMIA” IN PATIENTS WITH PREVIOUSLY UNIDENTIFIED CLINICAL CONDITIONS

D. Roccato1, S. Sciascia1, C. Naretto1, A. Barreca2, L. Scifetti1, L. Battaglia1, L. Viziello1, R. Fenoglio1, D. Ross1, L. Battaglia1, L. Solfietti1, L. Batta1, R. Fen1, D. Rossi1, A. Barreca2, L. Scifetti1, L. Battaglia1, L. Viziello1, R. Fenoglio1, D. Ross1

Background: This study describes a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinemia) or represents a separate entity.

Objectives: We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinemia) or represents a separate entity. We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinemia) or represents a separate entity.

Methods: Using a modified precipitation technique in hypo-ionic medium, we prospectively identified between 2008 and 2021 237 patients (median age 60.8 years [22–97], 137 females) having < 0.5% cryocrit and clinical suspicion of autoimmune disease. Of these 237 patients, only 54 (22.7%) had a history of HCV infection. One hundred and sixty-nine out of 237 patients (71%) had an established underlying disease, while 88 patients (38.6%) (median age 62.9 years [29–90], 35 females) did not show either laboratory markers or clinical symptoms consonant with an underlying aetiology. These cases were only trace amounts of cryoglobulins were defined as achieving a putatively idiopathic hypocryoglobulinemia. Nineteen of these 68 patients (27.9%) had a history of HCV infection. Twentyfour patients out of 68 (35.3%) were positive for rheumatoid factor (RF), while 25 (36.7%) patients had signs of complement consumption (i.e., C4 < 15 mg/dl and/or C3 < 80 mg/dl), and 36 (52.9%) had increased inflammatory indexes. Seven patients only had arthralgia and constitutional symptoms while 61 out of 68 (89.7%) presented with at least one of the three cardinal signs of cryoglobulinaemic vasculitis including skin lesions, peripheral nerve involvement, and glomerulonephritis. Fifty-one percent of the subjects had type III hypoglobulins. In patients with hypocryoglobulinemia the histologic features of glomerulonephritis (also examined by electron microscopy) resembled those of mixed cryoglobulinemia-associated glomerulonephritis.

Conclusion: In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinaemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

POS1179 USING ARTIFICIAL INTELLIGENCE TO IDENTIFY ANTI-NEUTROPHIL CYTOPLASMATIC ANTIBODY (ANCA)-ASSOCIATED VASCUITIS PATIENTS IN ELECTRONIC HEALTH RECORDS

J. Van Leeuwen1, E. Penne6, Y. K. O. Teng1, W. Leiden University Medical Center (LUMC), Nephrology Section - Internal Medicine Department, Leiden, Netherlands; *Northwest Clinics, Nephrology Section - Internal Medicine Department, Alkmaar, Netherlands

Background: Anti-neutrophil cytoplasmatic antibody (ANCA) associated vasculitis (AAV) is a rare, life-threatening, systemic auto-immune disease. Due to the low prevalence, multiple treating disciplines and poor registration, including ICD-10 classification, identifying AAV patients for (pre-)clinical studies, research and health care evaluation is challenging. Therefore, there is an urgent need to improve identifying these patients in health care organisations. Employing artificial intelligence (AI) – supported search engines are increasingly suggested to achieve this.

Acknowledgements: NIL.

Disclosure of Interests: None Declared.

DOI: 10.1136/annrheumdis-2023-eular.2295
**Objectives:** Reliably identify AAV patients in electronic health records (EHR) using an AI-based tool that incorporates text mining and Natural Language Processing (NLP).

**Methods:** The identification method consists of a search strategy combined with NLP-based exclusion. A search strategy to optimally identify AAV patients in electronic health records (EHR) was investigated. Validation was performed on an independent EHR system of a non-academic hospital with an established AAV cohort available for reference (n=84).

**Results:** The search strategy combined five queries based on disease description, laboratory measurements, medication and relevant specialties. In the determination of ANCA-associated vasculitis, 608 patients, including 197/203 (97.0%) AAV patients of the reference set and 148 newly-identified AAV cases confirmed by manual review. Employing NLP in the identification method improved the positive predictive value (PPV) from 57% (346/608 patients) to 78% (339/444 patients). These results were validated in an independent EHR system where the search strategy identified 333 patients, including 82/84 (97.6%) AAV patients of the reference set and 112 newly-identified AAV cases upon manual review. NLP improved PPV from 59% (194/333 patients) to 86% (192/223 patients). Negative predictive values and specificities were above 98% in all analyses.

**Conclusion:** We present an AI-based identification method to identify low-prevalent AAV patients in EHR systems. We demonstrated improved performance when adding NLP to the text-mining search strategy. Successful validation in an independent health organisation supports the applicability and transportability of this method which can be an important accelerator for research efforts and health care evaluation in AAV patients.

**POST180 CONCORDANCE IN THE CLASSIFICATION CRITERIA IN A PATIENT COHORT OF ANCA ASSOCIATED VASCULITIS**

**Keywords:** Validation, Vasculitis

O. iaremenko1, L. Petelytska2, V. Kravchenko3, Bogomolets National Medical University, The Department of Internal Medicine #3, Kyiv, Ukraine; Bogomolets National Medical University, The Department of Internal Medicine #3, Kyiv, Ukraine; Bogomolets National Medical University, The Department of Internal Medicine #3, Kyiv, Ukraine.

**Background:** Despite existing of different classifications criteria for ANCA-associated vasculitis (AAV), early diagnosing AAV is still challenging. Previous classification criteria do not include some of important diagnostic tests (for example, ANCA) or surrogate clinical markers and had insufficient specificity. According to the Vasculitis Patient-Powered Research Network study, the median time to diagnosis of vasculitis amounts 7 months and 73% of patients are misdiagnosed initially. Recently the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) have proposed the new classification criteria for AAV which corresponded only to the classification criteria of ACR 1990 and the EMA algorithm (3 EGPA, 1 U, 1 GPA), and one patient has not met any criteria. The new classification criteria of AAV demonstrated better agreement compared to the previous ones demonstrated better agreement with the established diagnosis of GPA (k 0.6 vs 0.3, sensitivity 88.0% vs 92.0%, specificity 70.6% vs 35.3% ) and MPA (k 0.5 vs 0.2, specificity 71.4% vs 14.3%, specificity 86.6% vs 100%), but worse agreement with the diagnosis of EGPA (k 0.8 vs 1.0, sensitivity 71.4% vs 100%, specificity 100% vs 100%). The observed agreement between the two classification criteria was slight for GPA (k 0.3) and MPA (k 0.2), but substantial for EGPA (k 0.8).

**Conclusion:** There is a slight agreement between ACR/EULAR2022 criteria and ACR1990 criteria/EMA algorithm for GPA and MPA.

**POST181 VALIDATION OF THE 2022 - AMERICAN COLLEGE OF RHEUMATOLOGY/EUROPEAN ALLIANCE OF ASSOCIATIONS FOR RHEUMATOLOGY CLASSIFICATION CRITERIA IN INDIAN PATIENTS WITH ANCA ASSOCIATED VASCULITIS**

**Keywords:** Vasculitis

A. Sharma1, P. Deo1, G. Naidu1, J. Samanta1, S. Mitra1, K. Sharma2, R. Nada2, V. Dhiri3, S. Jain3, R. Minz3, Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India; Post Graduate Institute of Medical Education & Research, Chandigarh, Medical Microbiology, Chandigarh, India; Post Graduate Institute of Medical Education & Research, Chandigarh, Histopathology, Chandigarh, India; Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India.

**Background:** 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria for classification of ANCA associated vasculitis need to be validated in different cohorts.

**Objectives:** The purpose of this study was to validate the recently published 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria for classification of ANCA associated vasculitis/AAV (Granulomatosis with Polyangiitis [GPA], Eosinophilic Granulomatosis with Polyangiitis [EGPA] and Microscopic Polyangiitis [MPA])

**Methods:** Patients with a diagnosis of AAV from Indian vasculitis registry (INVAR) cohort were included in the study. The new 2022 ACR classification criteria for AAV[1]–[3], 1990 ACR classification criteria for GPA and EGA, and the EMA Algorithm were validated in our cohort to assess their performance. The level of agreement was assessed using Cohen's kappa. The clinician's diagnosis was considered as the gold standard.

**Results:** A total of 302 patients diagnosed AAV with mean age of 42.8± 14.7 years were included. 58.7% were female and 42.3 % were male. Figure 1 show the distribution of AAV patients classified according to various diagnosis criteria. The new 2022 ACR classification criteria for GPA (kappa: 0.961; sensitivity: 99% and specificity: 99.9%), for EGPA (kappa: 0.981; sensitivity: 92% and 100%) had almost perfect agreement with INVAR cohort. Table 1 shows performance of EMA algorithm and the ACR 1990 criteria compared to the new 2022 classification criteria for AAV in the INVAR
cohort. Furthermore, predominant CNS or ocular GPA (if PR3/MPO negative) were missed by the new ACR classification criteria. EMA Algorithm missed cases of ANCA vasculitis where histology was not possible or ANCA was positive by IIF. Conclusion: The study showed the new criteria for AAV, had good performance in INVAR registry AAV patients. The new criteria had good sensitivity and speci-ficity for classification of GPA, MPA and EGPA compared to EMA algorithm.

POS1183 GENDER IMPACT ON BASELINE PRESENTATION AND OUTCOME IN ADULT IGA VASCULITIS

Keywords: Epidemiology, Gender/diversity issues, Vasculitis

K. L. Baud1, Y. Ramdani1, V. Maisons1, E. Pillebout2, J. F. Augusto3, N. Jourde-Chavannes1

Methods: We retrospectively study the data of the French retrospective multicenter cohort (IGAVAS), including 260 IgAV adult patients. Comparison of presentation and outcome were performed according to gender status (male vs. female).

Results: Of the 260 patients included, data from 259 patients were analyzed: 95 female and 164 male (one missing data). Compared to female, baseline disease presentation in male was similar for cutaneous involvement (n=164 (100%) vs. n=95 (100%), p=0.10), joint (n=99/164 (60%) vs. n=60/95 (63%), p=0.7) involvement, gastrointestinal involvement (n=93/164 (57%) vs. 43/95 (45%) p=0.093) and glomerulonephritis (n=120/164 (73%) vs. n=61/95 (64%) p=0.16).

Conclusion: Despite its limits, this study raises the question of a more severe disease in male terms of glomerulonephritis. This hypothesis is sustained by the fact that male compared to female were more severe more aggressively treated and present a poor short outcome whereas the long term outcome do not seem to differ. Altogether, these results raise the question of the gender as a new prognostic factor during the course adult IgAV.

Clinical cases

POS1183 DIAGNOSTIC CHALLENGES IN A PREGNANT PATIENT WITH SLE AND SYSTEMIC SCLEROSIS OVERLAP – PREECLAMPSIA, ACTIVE LUPUS NEPHRITIS OR RENAL CRISIS?

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction, Systemic sclerosis

K. Gheorghe1, K. Hellgren2, K. Gunnarsson3, Karolinska University Hospital, Rheumatology, Stockholm, Sweden; 2 Karolinska Institutet, Department of Medicine Solna, Division of Clinical Epidemiology, Stockholm, Sweden

Background: Pregnancy is an important issue for young women with inflammatory systemic disease and pose a clinical challenge.

Objectives: The aim of this case report is to underline the challenges to correctly diagnose pregnancy complications versus disease flare in pregnant women with overlap syndrome.

Methods: Clinical information collected from the patient's journal.

Results: A 26 years old woman was referred to Karolinska University Hospital because of Raynaud's phenomenon, sclerodactyly, skin rash, palpe ulcerations and recurrent finger ulcerations with necrosis, infections and self-amputation of distal phalanges. Interstitial lung disease was confirmed by high resolution CT and a restrictive pattern on lung function tests. Immunological analy-ses detected autoantibodies against Scl-70, ribosomal-P, SS-A, SS-B, Ku, as well as other autoantibodies with immunoprecipitation technique with varying titers over the years. Complement activation, anemia and lymphopenia were also present. The patient experienced muscle weakness and peripheral muscle MRI and muscle biopsy confirmed myositis. During follow-up she developed pericardial effusion and myocarditis. The patient was diagnosed with overlap syndrome with clinical and serological features of systemic sclerosis, SLE and myositis. The immuno-suppressive treatment over the disease course comprised hydroxychloroquine, methotrexate, azathioprine, nifedipine and low dose prednisolone. Later, treatment was switched to mycophenolate mofetil because of flares on the previous regimen. For the digital ulcers, she was treated with nifedipine, sildenafil and iloprost infusions. Despite medical advice on pregnancy risks during active disease, the patient stopped medication with mycophenolate at the age of 35 years and became pregnant. Enalapril, spironolactone and sildenafil were discontinued and she was referred to the specialist maternity care. The pregnancy evolved without complications until week 18 when the blood pressure (BP) began to rise.
A CASE OF DELAYED DIAGNOSIS OF MUCKLE WELLS SYNDROME- AN EXTREMELY RARE BUT IMPORTANT DIFFERENTIAL OF INFLAMMATORY ARTHRITIS IN A RHEUMATOLOGY CLINIC

Keywords: Rare/orphan diseases, Inflammatory arthritis

A. Anjum 1, R. Davies 1, R. Asif 2, Cardiff & Vale University Health Board, Department of Rheumatology, Cardiff, United Kingdom; 2Aneurin Bevan University Health Board, Department of Rheumatology, Newbridge, United Kingdom

Background: Muckle wells syndrome (MWS) is one of the rare clinical pheno-types of Cytopyrin associated periodic syndromes (CAPS), driven by Interleu-kin-1 mediated systemic inflammation. [1] A typical presentation includes episodic fever, urticarial rash and arthralgia but can also result in episodic inflammatory arthritis and sensorineural hearing impairment. Secondary amyloidosis is the most feared complication especially in patients with untreated active disease.[2]

Objectives: We present a case of a 32 years old male, with history of episodic pain and swelling of the right knee for 2 years before presentation to rheumatology clinic.

Methods: Over the years, prior to rheumatology review he was seen by multiple specialties for varied unexplained symptoms including ENT for progressive sensorineural hearing impairment, dermatology for intermittent childhood onset eczema-tous rash and by ophthalmology for episodic idiopathic iritis and uveitis. He was also seen by haematology for an episode of cervical lymphadenopathy with no defi- nite cause identified. There was no history of inflammatory back pain, psoriasis or Inflammatory bowel disease. Of note, his father had severe sensorineural hearing loss and his brother had a diagnosis of undifferentiated inflammatory arthritis at a young age. On initial rheumatology assessment he had a moderate knee right knee effusion and an erythematous non-specific rash over his upper back. A review of previous investigations showed raised inflammatory markers (CRP 93). A prior MRI right knee showed areas of synovial hypertrophy with a moderate knee effusion.

Results: Subsequent genetic tests confirmed a low activity of NLRP3, as well as ENA CCP Ab, ANA, ENA, ANCA, HLA B27 and HLA B-8. The initial rheumatology impression was of an isolated seronegative inflammatory arthritis of the right knee but given other unexplained symptoms and family history we investigated for autoinflammatory disorders. Subsequent genetic screen was positive for NLRP3 gene confirming Muckle Wells syndrome as the unifyng diagnosis. This case was also discussed with the National Autoinflammatory Disease Centre at the UCL London and he has recently been commenced on Anakinra.

Conclusion: Targeted IL-1 inhibitors can prevent secondary amyloidosis. Effect on hearing impairment is uncertain but can be reversed in some cases. The heterogeneity of presentation poses a significant diagnostic challenge, how-ev-er given the clear efficacy of available treatment options, an early diagnosis is extremely important to improve symptoms and prevent serious organ damage from secondary amyloidosis.

POS1185
HIGH PHENOTYPIC VARIABILITY IN THREE SIBLINGS WITH ADA2 DEFICIENCY

Keywords: Cardiovascular disease, Vasculitis, Genetics/epigenetics

E. Scuolo 1, K. Paciaroni 2, E. Sangiorgi 3, I. Quinti 1, F. Pulvirenti 1, 1Sapienza Università di Roma, Molecular Medicine, Roma, Italy; 2Presidio Ospedaliero Sant’Antonio, UOSS Ematologia, Roma, Italy; 3Policlinico Universitario Agostino Gemelli, Scienze della vita e sanità pubblica, Roma, Italy; 4Policlinico Umberto I, Internal Medicine and Infectious Disease, Rome, Italy

Background: Deficiency of adenosine deaminase 2 (ADA2) is a monogenic disease caused by biallelic mutations in the ADA2 gene. The phenotypic spectrum is broad, most commonly including fever, early-onset vasculitis, stroke, and hematologic dysfunction. Initially considered a childhood disease, the first presentation is now being reported well into adulthood. Vasculitis manifestations closely resemble polyarteritis nodosa, vasculitis involving the skin, muscle, or nervous system in adults, and lead to multiorgan involvement and ischemic or hemorrhagic stroke. Immunological manifestations include hypogammaglobulinemia and recurrent infections. Currently, TNF inhibitors are the treatment of choice to reduce the risk of vascular events and infection but seem not effective for immunodeficiency and haematologi-cal manifestations, which require hematopoietic stem cell transplantation.

Objectives: To describe the clinical features, genotype, and treatment approaches of subjects bearing the same ADA2 homozgyous pathogenic var-iants, but presenting a different clinical expression.

Methods: To describe the clinical features, genotype, and treatment approaches of subjects bearing the same ADA2 homozgyous pathogenic variant, but pre-senting a different clinical expression.

Results: The proband was a 57 years-old female with severe neutropenia and recur-rent infection, born out of consanguineous marriage. Her past medical history was characterized by recurrent episodes of fever during childhood. At the age of 18, she developed erythema nodosum, the purpura of her limbs, and arthritihs of the hands and feet treated with steroids. In her forties, the fever became more recurring and she suf-fered from recurrent vaginitis by Candida albicans, worsening pyorrea and oral ulcers, with recurrent infections. At 50 years, she was diagnosed with diabetes mellitus needing insulin treatment. At 57 years, she was referred to the hematologic unit for severe neutro-penia and she started treatment with granulocyte colony-stimulating factor. When he was referred to our hospital, she was afebrile with stable vital signs. Laboratory tests showed severe neutropenia, with normal acute-phase reactants. The bone marrow smear documented a late maturation arrest, with an increased number of cytotoxic lymphocytes CD3+CD8+. Autoantibody-panel including ANA, anti–double–stranded DNA andENA antibodies were negative, and the rheumatoid factor was positive. The patient’s family history was positive for a 62 years-old brother with a prior left thalamic nucleus haemorrhage, a 57-year-old sister with severe hypogammaglobulinemia and neutropenia, recurrent fever and livedo reticularis, and one sister who died at 47 from a heart attack. Exome analysis identified the proband and her siblings as homozy-gous for the (c.7467-T>C p.Leu249Pro) (NM_001282252) variant of the ADA2 gene (OMIM:607757). Anti-TNF treatment was prescribed for all patients and immunoglobulin treatment was prescribed for the sister with hypogammaglobulinemia. Despite being informed of the risk, all the patients declined the treatment.

Conclusion: This case familiar case demonstrated the wide range of phenotypic vari-ability in ADA2. The search for ADA2 mutations and the assessment of ADA2 activity should be considered with the familiar history positive for the association of hypogammaglobulinemia, inflammatory conditions, and stroke, even if in different relatives. Familiar cases of ADA2 provide a unique insight into the disease's wide range of phenotypic variability. Further studies are needed to determine differences in the underlying pathophysiology of different phenotypes in ADA2.

HPR Patients’ perspectives, functioning and health (descriptive: qualitative or quantitative)

**Keywords:** Cognitive function, Outcome measures, Health services research

A. Özçakar1, O. Caglar2, G. Coşkun1. 1Hacettepe University Faculty of Physical Therapy and Rehabilitation, Musculoskeletal Physiotherapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Orthopedics and Traumatology, Ankara, Turkey

**Background:** Patient-reported outcome measures, including joint-specific parameters of activities of daily living, such as joint awareness, are increasingly recognized as an important part of post-surgical outcome assessment [1].

**Objectives:** The aim of this study was to examine the relationship between artificial joint awareness and emotional status in patients who have undergone total hip arthroplasty (THA) surgery.

**Methods:** In this study, volunteer patients aged between 40-65 years who had undergone THA surgery and at least 1, a maximum 3 years after surgery were included. Artificial joint awareness was evaluated with the Forgotten Joint Score-12 (FJS-12) scale. It is a scale that questions awareness of artificial joint during various daily living activities from the patient's perspective in order to determine the ability of patients to forget artificial hip joints after THA surgery [2]. High scores indicate how much (%) the patient can forget the operated side of the patient and adapt to their life. In other words, a high score indicates a high degree of 'forgetting' the artificial joint – i.e. a low degree of awareness. A 5-point Likert system is used in the scoring. The emotional status of patients was determined by Hospital Anxiety and Depression Scale (HADS). It includes anxiety (HADS-A) and depression (HADS-D) subscales. It consists of a total of 14 items, 7 of which are about anxiety and 7 of which are investigating symptoms of depression [3]. Pearson correlation analysis was used according to distribution of the data to determine relationship between the variables. The significance level was accepted as p<0.05.

**Results:** Sixty patients with THA, aged 53.46±7.9 years, were included in the study. Mean FJS-12, HADS-A, and HADS-D scores were 32.68±6.54, 7.27±3.2, and 5.27±2.5, respectively. A moderately and statistically significant correlation was found between FJS-12 and HADS-A and HADS-D (r=0.466, p<0.004; r=0.483, p=0.003 respectively).

**Conclusion:** The results of the current study showed that the adaptation of the artificial limb to daily life is poor and was correlated with emotional status. These results may show that worsening of patients' emotional status may contribute to development of artificial joint awareness. Therefore, also take into consideration the emotional state of patients with THA while applying therapeutic approaches aiming to decrease awareness of artificial joint and increase adaptation of artificial limb to daily life may increase the effectiveness of rehabilitation.

**Participants’ view on the feasibility of INSIELMA - A new interdisciplinary nurse coordinated self-management intervention to people with inflammatory arthritis and substantial disease impact - A qualitative evaluation**

**Keywords:** Inflammatory arthritis, Qualitative research methods

N. Blum1, B. A. Esbensen1, M. Østergaard2, A. Bremender3, O. Hendricks3, L. Lindgren1, L. Andersen1, K. V. Jensen1, J. Primdahl3. 1Copenhagen University Hospital, The Department of Rheumatology and Spine Diseases

- Copenhagen Center for Arthritis Research, Glostrup, Denmark; 2University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; 3University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark

**Background:** Despite continuous improvements in antirheumatic pharmacological treatment, many people with inflammatory arthritis (IA) still report substantial disease impact. Based on the framework for complex interventions [1], we developed a self-management intervention (INSIELMA)[2]. Based on shared decision-making, which included an initial assessment and a goal setting process a rheumatology nurse coordinated interdisciplinary support and available offers in primary care to achieve the patients’ individual goals. A feasibility test of the six-month intervention encompassed 19 patients with IA and substantial impact of the disease.

**Objectives:** The objective of this study was to explore the participants’ experience of feasibility, acceptability, and potential benefit from participation in the INSIELMA intervention.

**Methods:** Individual semi-structured interviews were conducted with participants in INSIELMA. Thematic analysis was applied [3].

**Results:** Fifteen participants were interviewed (9 women, 6 men, aged 44-75, 17-75 mln.) The participants associated the benefits they experienced from the intervention to the impact IA had on their everyday lives.

The analysis derived four overall themes.

1. A new opportunity. Participation in INSIELMA was experienced as an opportunity to improve, reduce challenges, or change issues they felt they had fought alone until now. Some expressed worries that their situation was too complex to be able to contribute to the study and some participated to contribute to scientific IA evidence.

2. The importance of person-centred goals. The individual goals encompassed both physical, social, and emotional life skills. When expectations and goals were aligned, it facilitated a positive outcome. The empathic support and coaching from the nurses, who listened, motivated, and understood their problems were considered especially valuable. Time between consultations to work with goals at home was pointed out as important to experience progress.

3. A little nudging means everything. Several participants expressed that the intervention had contributed with new or refreshed knowledge and motivation to change habits. Some would like continued follow-up with the nurse after the end of the study to stay committed. Also some suggested that this type of intervention should be a general offer for all patients with IA. Having access to a physiotherapist and an occupational therapist with rheumatology experience for exercise support adapted to the participants' needs and abilities was especially important for them.

4. I got more than I wished for. The intervention was experienced as feasible and meaningful, and the overall impression was positive. Several cried tears of joy and gratitude as they experienced decreased symptom load, improvement in physical strength, mobility, and sleep as well as increased energy and coping. Two had experienced no change, of which one had resumed physical activity after several years. The participants expressed hope for the future as they had new tools and habits to prevent problems and manage symptoms, which resulted in motivation to work towards new goals.

**Conclusion:** Patients found the INSIELMA intervention feasible. They experienced decreased disease impact and increased activity level, facilitated by empathy and support from the intervention.

Objectives: To analyse experiences, facilitators and barriers of telemonitoring the pulmonary function in SSC-ILD patients.

Methods: This study was embedded in a longitudinal study on the validity of detecting progressive ILD with weekly home spirometry in adult SSC patients, fulfilling the ACR-EULAR criteria with a disease-duration ≤ 5 years and a maximum of immunosuppressive treatment of 8 weeks. Using a Bluetooth-enabled handheld spirometer, measurements are collected via a mobile application for smart devices with results being visible, as graphs and bar charts, for both physician and patient. The weekly measurements are evaluated by a physician and an extra hospital check-up will be scheduled if results decrease. This system has proven to be feasible in SSC patients in our pilot study [3].

In patients, who used home spirometry for at least 3 months, semi-structured interviews were conducted and audio-records were transcribed. Patients were selected using purposive sampling based on age, treatment for ILD and course of pulmonary function in telemonitoring (>5% decline/stable) till data-saturation was achieved (i.e. no new codes in the last 2 interviews). Interviews were coded by 2 researchers independently using inductive thematic analysis.

Results: In total 13 patients (8 female/5male) were interviewed from whom 3 patients had > 5% decrease in pulmonary function during the observation period. The age ranged from 36-75 with a median of 58 year. Five main themes were extracted: telemonitoring routine, impact of telemonitoring, trust in telemonitoring, contextual factors and implementation in regular healthcare (Figure 1). Most patients perceived it as reassuring to see stable results weekly, though the moment itself might be tensive. Moreover, the possibility to detect progressive disease earlier was appreciated. One patient, however, preferred disease activity measurement (during breathing cycle in hospital vs. single breath at home).

Some patients placed fluctuations of measurement within limits of normal in perspective, while others experienced negative feelings in case of a decreased value. Experienced advantages of telemonitoring were being in the lead, insight in disease course (for some resulting in less confronting hospital visit), increased trust in health, decreased fear of progression, and reduced dependence on hospital visits. Most patients trusted the results of telemonitoring, although some trusted the hospital measurements more, because of external guidance from an analyst (leading to more motivation and unbiased results), and the manner of measurement (during breathing cycle in hospital vs. single breath at home).

Understanding the rationale behind telemonitoring is an important facilitator, whereas possible barriers to perform weekly home spirometry are excessive saliva production (as it hinders proper function of the spirometer), confrontation with the disease, and older age. Most patients advocated to implement telemonitoring in healthcare and appreciated an accompanied reduction in hospital visits, although others viewed the regular physical contacts and control of other disease features as important. It was recommended to provide information about limits of normal values or regular feedback.

LUNG AND MYELOPROLIFERATIVE NEOPLASMS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH JANUS KINASE INHIBITORS: A REVIEW OF THE LITERATURE

Keywords: bDMARD, Malignancy, Rheumatoid arthritis

O. Hamed1, M. Yasmine1, S. Miadi1, F. Aila1, H. Boussaa1, L. Souabni1, K. Cueninche1, S. Kassab2, S. Chekili3, K. Ben Abdelghani3, A. Laatar3,1,1Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia

Background: Janus Kinase inhibitors (JAKi) have been shown to be effective in the therapeutic strategy of rheumatoid arthritis (RA). However, an increased risk of developing malignancy has been reported in previous literature [1].

Objectives: This review aimed to investigate the risk of lung carcinoma and subsequent myeloproliferative neoplasm (MPN) in RA patients treated with JAKi.

Methods: We conducted a literature review in order to identify cases of lung carcinoma and MPN associated to JAKi in RA patients. A comprehensive search was conducted using PubMed and Scopus. The databases were searched from 2015 until date December 2022. No restrictions were applied in terms of study design, setting, country, or time frame. For PubMed, the search was carried out using a strategy employing the combination of synonyms of “pulmonary neoplasm” terms related to “JAK inhibitors”, and terms related to “rheumatoid arthritis.” For Scopus, the previous terms were searched in the article title, abstract, or key-words. We also did manual research on reference lists of retrieved relevant articles. Articles were eliminated if they had duplicate titles, did not contain the key-words, or included the words “review,” “expert’s opinion,” or “qualitative.” In this review, we included prospective or retrospective case reports and case series conducted on JAKi and lung carcinoma or MPN.

Results: The initial search yielded 153 papers. Following duplicate elimination, we screened for 119 papers. Only eight papers were finally selected for analysis and met inclusion criteria. The mean number of RA patients included was 2422 [486-6194]. Standardized incidence ratio of lung carcinoma and MPN ranged from 0.17 to 0.19 and 0.01 to 0.1, respectively. Most papers raised the possibility that RA patients treated with JAKi may have a markedly higher rate of development of lung carcinoma (95% CI [1.51 - 1.79]) or MPN (95% CI [2.05 - 2.96]) compared to patients who did not receive the treatment. The Table 1 exposes the main characteristics of the nine studies retained in this review.

*SIR: Standardized incidence ratio, *CI confidence interval

Conclusion: Our study showed that JAKi was associated with an increased risk of development of lung malignancy and lymphoma. Although the risk of malignancy is increased compared with the general population, it is still similar to that seen in the overall RA patients.
Background: It is well known that genetic factors and environmental triggers contribute to the inflammatory process and onset of systemic lupus erythematosus (SLE). Yet, other contributors may still be unknown, and few studies have to date systematically explored patients’ views on what caused SLE onset. In a longer perspective, we also need to pay more attention to health literacy, and to patients’ understanding of their disease since these aspects are important for treatment compliance, patients’ perceptions of health and patient education.

Objectives: To explore patients’ thoughts of the cause of SLE and to analyse their reports in relation to perceived health and quality of life.

Methods: Adult patients with SLE (≥ 4 ACR criteria) recruited to a cohort study in tertiary care. The participants answered the written question “Do you have any thoughts of why you got SLE?” and additional questions of perceived SLE activity during the last three months (score 0-10, 0= no activity), SLE health last week (score 0-100, 0=good SLE health) and current general health (score 0-100, 100=full health). The participants’ free written answers were categorized according to the content. We explored if patients’ age, educational level, disease duration as well as perceived health differed between the categories.

Results: 375 patients were included. The main question regarding their thoughts of why they got SLE was answered by 290 patients (77%), mean age 48 years, range 18-87, mean disease duration 15 ±14 years. The replies on the health scales ranged from minimum till maximum. SLE activity was low to moderate (mean 4.2 ±3), perceived SLE health mean 34.7 ±25.9 and current general health mean 63.1 ±21.0. The highest reported level of education was university education for 47% and high school for 36%. Among the patients who answered the main question (n=290), 33% (n=95) answered that they had no idea/thoughts of why they got SLE. Men (p = 0.041) and persons with lower educational level (p = 0.038) were more common in this group, also reporting slightly better general health (p=0.050) than the group that had explicit thoughts of why they got SLE. Age, disease duration or perceived SLE parameters did not differ between the two groups. The answers of patients’ thoughts of why they got SLE were sorted into categories: genetics (n=82), stress/trauma (n=65), infections/immunizations (n=56), hormones/treatment (n=28), lifestyle behavior (n=28), treatment/disease other than SLE (=26) and environmental factors (n=5). A majority (n=135, 69%) wrote one potential factor of why they got SLE, two factors were reported by 49 patients (25%), one patient wrote five potential reasons. It was exclusively answers from women that could be categorized as “hormones/treatment” or “treatment/diseases other than SLE” and only one man wrote a statement of stress/trauma as potential trigger of SLE. Patients in the category “hormones/treatment” had shorter disease duration (p=0.029), higher perceived SLE activity (p=0.011) and worse general health (p=0.002) compared to those that had no statement that could be sorted into the category. Only five patients reported environmental triggers and these perceived worse SLE health (p=0.022) and worse general health (p=0.038). Patients who reported stress/trauma as potential triggers of SLE were not in a larger extent of a lower education level (p=0.027) than those who did not report stress/trauma as a trigger.

Conclusion: Beside genetic factors, a prominent number of patients in this study reported stress/trauma or hormones as important triggers for developing SLE. In these groups perceived health and educational levels had different patterns. Additionally, infections/immunization were perceived as triggers for SLE but without the same difference in perceived health or educational level. Further studies should extend these results and investigate patients’ perceptions of triggers for SLE flares, and high disease activity, information which can enhance our understanding of factors that may contribute to important aspects of SLE and patients’ perceptions of health.

POS1191-HPR ULTRASONOGRAPHIC AND FUNCTIONAL CORRELATION OF THE FEET IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Ultrasound, Systemic lupus erythematosus

L. Cano García1, J. García-Campos2, F. Ortiz-Márquez1, A. Reinoso Cobo1, L. Ramos Petersen1, J. Marco-Lledó3,1, Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA), Rheumatology, Málaga, Spain;2;3Universidad Miguel Hernández; Instituto de Investigación Sanitaria y Biomédica de Alicante, Hnos. Mª, Alicante, Spain;3Universidad de Málaga, Departamento de Podología, Málaga, Spain

Background: Systemic lupus erythematosus (SLE) is a chronic immune-mediated disease with involvement of various organs[1,2]. El 95% of patients with SLE have musculoskeletal involvement[1], most often in the form of arthralgias or non-erosive arthritis affecting mostly the hands and knees. A subgroup of patients with SLE, which is seen with increasing frequency, later develops a deforming arthropathy as a result of laxity of ligaments and peritendinous apparatus resulting in joint subluxations and tendon ruptures which is part of the accumulated damage of the disease. The foot is a heavily affected structure that may initially go unnoticed, but can lead to significant disability.

Objectives: To determine the relationship between inflammatory activity measured by ultrasound in metatarsophalangeal (MTP) and questionnaires of foot functionality, hand deformities and SLE activity.

Methods: A cross-sectional study was performed. Thirty-six subjects with a diagnosis of SLE in the Rheumatology Unit were consecutively recruited between March and June 2022. Inclusion criteria were: patients with SLE diagnosis according to EULAR/ACR 2019 criteria, with at least one year of evolution and age equal or older than 18 years. A Rheumatology nurse collected information on socio-demographic data, questionnaires and ultrasound scans. The SLE activity questionnaires completed were: SLEDAI and SLICC, quality of life: EQ-SD, foot function: FFI (Foot Function Index), FAAM (Foot and Ankle Ability Measures Index). As for hand malformations collected were: Jaccoud arthropathy, non-reducible arthritids, z-finger, grommet finger, non-reducible arthritids, burst finger and goosenock finger. A descriptive, bivariate and R-Pearson correlation analysis was performed.

Results: Thirty-six SLE patients (97.2% female) with a mean (SD) age of 49.31 (11.4) years with a range 23-66 years participated. A total of 30 patients (83.3%) showed at least one MTP synovitis, the most frequent being 2nd MTP left (58.8%) and right (44.4%), followed by 1st MTF right and left (41.7%). The number of patients with and without ultrasound synovitis, as well as the degree of synovitis and Doppler signal in each joint are shown in Table 1. A significant direct correlation was observed between inflammatory activity with Doppler in the 1st MTF of the right foot with the SLICC (r=0.439; p=0.007) and SLEDAI (r=0.608; p<0.001) questionnaire, as well as an inverse relationship between synovitis in the 1st toe of the right foot with the FPI questionnaire of the right foot (r=-0.340; p=0.040) (Table 2). Likewise, a significant relationship was observed between deformity in the hands with the synovitis of 5 right (p=0.042) and left (p=0.005) MTFs.

Conclusion: Ultrasound synovitis in MTFs is common in SLE patients and is associated with disease activity, some deformities and functionality.

RESULTS:

We recruited 200 patients. The mean age was 55.1 ± 12.0 years, and the majority were women (91%). More than half of the population (57.5%) was illiterate, and only 5.5% of the patients had a university education. ¾ of the population was urban (74.5%), and 93% were not working. 64.5% correctly identified the nature of RA as an autoimmune disease, and 26% correctly recognized that RA is a chronic, disabling condition that impairs quality of life.

Objectives: The objective of the study was to evaluate the knowledge and attitude of Moroccan patients with rheumatoid arthritis, and to determine the factors associated with them. Thus, it will be possible to set up a targeted education program for a better adherence to treatments.

Methods: This is a descriptive and analytical monocentric study of patients followed up for RA at Al Ayachi University Hospital, Sale, Morocco; and of patients who are members of the Moroccan Association for the fight against Rheumatoid Arthritis (AMFRA), from December 2021 to July 2022. The consent of the study population was free and informed. The interview questionnaire was developed by the team of rheumatologists and included sociodemographic data, the patients' knowledge about their disease, the treatments and their side effects, the follow-up and the patients' attitude toward self-medication. A score was indicated between 0 and 10 and represents the rate of correct answers per patient.

**CONCLUSION:** IF was associated with significant improvement in RA and SPA activity. It is a promising non-pharmacological therapeutic option for patients with RA and SPA. Larger sample studies with control groups are needed to confirm these findings.

**Keywords:** Reproductive health and planning (FP), and managing a high-risk pregnancy should be prioritized in the rheumatology consultation to achieve shared and respectful decision-making [1]. Lack of knowledge of reproductive health and poor communication during the consultation may lead to increased pregnancy complications in patients with ARDs.

**Objectives:** To describe and analyze patients’ experiences with ARDs on reproductive health issues at the clinic of pregnancy and reproductive health in rheumatology (CEER) in Mexico.

**Methods:** A descriptive qualitative study was conducted using semi-structured interviews following an interview guide. Women of childbearing age, suffering from ARD, with different socioeconomic, cultural, disability, and sexual diversity conditions were invited to participate. The face-to-face or virtual interviews were recorded and transcribed. A multidisciplinary team of researchers performed an independent and blinded thematic analysis.

**Results:** Twenty-one patients participated. The age media was 28 years (yrs.), 38% were married, 28.5% were free union and 28.5% were single; 33.3% were pregnant, 38% were in the preconception stage with the desire of pregnancy and 28.5% women who have already had children. The main rheumatologic diagnoses were rheumatoid arthritis (47.6%), systemic lupus erythematosus (47.6%), and mixed connective tissue disease (4.7%). Three main themes were identified: medications related to pregnancy and lactation, contraceptive methods and pregnancy planning (Table 1).

**Conclusion:** The experiences of patients with rheumatic diseases were diverse, and the amount of biomedical knowledge of RH issues was limited in FP decision-making, and prenatal or postnatal care. The patients recognized the relevance of a multidisciplinary team led by their rheumatologist to generate confidence in the quality of information and allow better decision-making according to patients’ beliefs, preferences, and reproductive rights.

**Background:** Foot and ankle involvement is common and debilitating in rheumatic and musculoskeletal diseases (RMDs), but outcomes in research and clinical practice are often inconsistently measured and may not be meaningful to patients. Outcome inconsistency contributes to lack of high-quality evidence to determine the effectiveness of foot and ankle treatments [1].

**Objectives:** To understand what outcomes are important to patients living with foot and ankle disorders in RMDs through an exploration of symptoms and impacts, and to establish how these outcomes can be measured in existing research studies.

**Methods:** A qualitative systematic review of interview and focus group studies involving patients with foot and ankle disorders in RMDs (inflammatory arthritis, osteoarthritis, crystal arthropathies, connective tissue diseases and musculoskeletal conditions in the absence of systemic disease) was undertaken. A scoping review of clinical trials and observational studies comparing conservative, pharmacological or surgical interventions for these disorders was also performed. Seven databases (Ovid Embase; Ovid MEDLINE; CINAHL; Psycinfo; Cochrane Database of Systematic Reviews; CENTRAL; PEDro) were searched from inception to March 2022. All data from the results sections of qualitative studies were extracted, coded and synthesised to develop themes, whilst outcomes measured in quantitative studies were extracted and tabulated. Confidence in the qualitative findings was assessed using the GRADE-CERQual (Confidence in the Evidence from Reviews of Qualitative research) approach, incorporating Critical Appraisal Skills Programme quality appraisal [2]. Patient and public involvement contributors were involved throughout both reviews, in the design, analyses and discussions about the findings.

**Results:** Thirty-four studies were included in the qualitative review, whilst 150 studies (n=83 randomised trials) were included in the scoping review. The majority of studies included patients with foot and ankle disorders in rheumatoid arthropathies (n=18 qualitative studies, n=43 quantitative studies) or osteoarthritis (n=5...
 qualitative, n=96 quantitative). Six themes were generated from the qualitative synthesis: pain, change in appearance, activity limitations, social isolation, work disruption and emotional distress. Themes were closely related; foot/ankle pain and deformity and subsequent limitations in footwear and clothing affected emotions and led to restrictions in physical, social and work activities, which caused further distress. Based on grading of the evidence, we had moderate confidence that most of the review findings represented the experiences of patients with foot and ankle disorders in RMDs. Foot/ankle pain (n=117 studies) and foot/ankle function (n=102 studies) were the most commonly measured outcomes identified in the scoping review; social function, occupational function and emotional status were rarely reported.

Conclusion: This is the first study to explore patients' experiences of foot and ankle disorders in RMDs alongside currently measured by clinicians and researchers. Our findings highlight that these disorders impact on multiple areas of patients' lives, both physically and psychologically. Pain was the predominant symptom experienced by patients and the most commonly measured outcome in existing research, but other outcomes that are important to patients should not be overlooked by clinicians and researchers. Our findings can guide patient-centred care and measurement of outcomes within clinical practice and future research.

POS1198-HPR HEALTH-RELATED MOBILE APPLICATIONS IN RHEUMATOID ARTHRITIS: WHAT ARE THE PATIENTS’ EXPECTATIONS?

Keywords: Self-management, Rheumatoid arthritis, Telemedicine

E. Hannachi1, M. Yasmine1, S. Miladi3, A. Fazaaz1, H. Boussaa1, K. Ouenniche1, L. Souabni2, S. Kassab2, S. Chekili2, K. Ben Abdelghani2, A. Laatar1. 1Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia

Background: The use of mobile phone applications for the management of rheumatic diseases (RD) has grown significantly these past few years [1]. Nevertheless, the success of these applications requires identifying the educational needs and interests of patients with RD.

Objectives: The purpose of our study was to investigate the expectations of rheumatoid arthritis (RA) patients regarding mobile applications in managing their disease.

Methods: We conducted a cross-sectional survey in our rheumatology department including RA patients, fulfilling the ACR/EULAR 2010 criteria. They were invited to respond to a questionnaire related to the utility of a mobile application in managing their disease. We evaluated their point of view on the desired functions of a smartphone app, the required content as well as the preferred design.

Results: The study included 40 RA patients: 36 females (90%) and 4 males (10%). The mean age was 52.25±14.4 years [21-78]. The mean disease duration was 11.97±6.69 years [1-29]. Two items were considered important and concerned the ability to contact the doctor when necessary and discuss their symptoms (72%), as well as the ability to check laboratory results (72%). Other features listed as useful were reminder date of clinic appointments (65%), and reminder of hours’ medication intake (60%). Nearly half of the patients expected the app to include educational videos (52%), exercise strategies to feel better (52%), ways to improve lifestyle habits (sports, sleep, professional activity, and dietary habits) (52%) and information about alternative treatments (55%). When asked about “what kind of health-related information should be tracked or monitored using a smartphone application?”, the most requested data to monitor concerned disease symptoms tracking (45%) using a validated measures of disease activity (43%), pain and fatigue (52%) using pain and general well-being questionnaires (41%) as well as arthritis-related functional scores (42%). Regarding the design, the application should be simple (68%), quick (63%), with clear font (44%). Moreover, it shouldn't

Conclusion: An increased prevalence of axial articular manifestations has recently been reported in primary Sjögren’s syndrome (pSS)[1] and as radiologic findings associated with inflammatory back pain (IBP) are not well documented in pSS patients.

Objectives: To assess the prevalence of IBP and its association with magnetic resonance imaging (MRI) detected auto-inflammatory and structural changes of sacroiliitis in pSS patients with IBP.

Methods: In this cross-sectional study, consecutive pSS patients fulfilling ACR/EULAR classification criteria and age- and sex-matched healthy controls (HC) were screened for IBP according to the Calin, Rudwaleit and ASAS IBP criteria.[2] Sacroiliac MRI imaging of patients with IBP was performed and SpA features in the ASAS Classification Criteria for Axial Spondyloarthritis (SpA) were questioned. Two radiologists assessed sacroiliac joint MRIIs (SLUMRI) for the cut-off values for a possible diagnosis of axSpA using ASAS defined lesion definitions. Cut-off values were defined previously by Maksymowych et al.[3] The First questionnaire was used to evaluate the relationship between fibromyalgia and back pain.[4]

Results: A total of 202 pSS patients meeting the ACR/EULAR classification criteria and 124 healthy controls were included. The mean age (mean (SD)=52.8 (11.9)) and sex distribution in pSS (female/male: 198/4) was similar to HC (51.5 (9.2), (p=0.3) and female/male: 119/227 S, (p=1), respectively) IBP was more prevalent in pSS (for pSS n(%): 51 (25.2), for HC n(%): 25 (20.2), p=0.001). SIJ/MRI was available in 49 patients with IBP. The mean (SD) age of onset of IBP was 33.6 (5.8). The mean (SD) duration of the IBP of the patients with pSS was 18.9 (10) years. pSS patients with IBP had significantly higher scores of the First questionnaire (patients with IBP mean (SD): 3.9 (1.7), patients without IBP: 2.8 (1.9), p<0.001). A total of 12 (24.5%) patients could meet the an axSpA diagnosis with a PPV of ≥95% as defined by Maksymowych et al.[3] Of these 12 patients, two with edema in the sacroiliac joint, nine with erosions, and four with fat metaplasia could be diagnosed as axSpA based solely on SJMIRI findings.

Conclusion: Low back pain meeting the IBP criteria is highly prevalent in pSS, and a quarter of these patients may have a radiologic diagnosis of axSpA. However, axSpA-associated features are absent in most patients, and very few meet the ASAS classification for axSpA. The presence of increased fibromyalgia may lead to an over-interpretation of radiologic features in the majority of these patients.

IMPROVING THE UPTAKE OF ELECTRONIC PATIENT REPORTED OUTCOME MEASURES IN A SPECIALISED AXIAL SPONDYLOARTHRPATHY CLINIC

Keywords: Patient reported outcomes, Spondyloarthritis, Outcome measures

J. Jade1, Z. Cox1, E. Fox1, R. Tattersall1, L. Dunkley2, 1Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom; 2Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom

Background: Sheffield Teaching Hospitals (STH), UK, has a specialised axial spondyloarthritis (axSpa) clinic run by a rheumatology consultant and physiotherapist with special interest in this area. BASDAI and BASFI patient reported outcome measures are used to assess disease activity and response to treatment, in line with national guidelines. STH has invested in MyPathway (MP), an electronic patient messaging system used for patient information, appointments and electronic patient reported outcome measures (ePROMs). The data can also be viewed at a system level on a clinician dashboard. Prior to 2020 the uptake of ePROMs was low in the axSpa clinic. The move primarily to telephone consultations in March 2020, due to the COVID-19 pandemic, created an opportunity for increasing the use of MP for ePROMs collection to enable improved remote monitoring of patients with axSpa.

Objectives: This quality improvement project aimed to increase the use of electronic BASDAI and BASFI (ePROMs) in the axSpa clinic.

Methods: A multi-pronged approach has been taken since March 2020 to increase ePROMs collection and improve their use. Each appointment was used as an opportunity to discuss and recruit patients to MP. Clinicians invited each patient to join MP and sent them a link after their appointment. QR codes were then added to all rheumatology patient letters encouraging patients to register. A pathway was set up that automatically sent a prompt to patients registered on MP to complete their BASDAI and BASFI questionnaires prior to clinic appointments. Clinicians began logging into MP to view scores during appointments to provide patients with real-time feedback. A mixed methods approach was used to assess the uptake of ePROMs over time. We tracked MP registration rates and BASDAI completion rates as the key outcome measures, using a run chart to assess special cause variation. We undertook a patient focus group to explore attitudes towards ePROMs, key barriers and opportunities for further improvement.

Results: The total number of axSpa patients seen in the specialised clinic (named LADAS) who have registered with MP has increased from 56 (35.9%) in January 2019 to 200 (58.9%) in September 2022. There has been an improvement in the BASDAI completion rate, with 80% of patients completing more than one BASDAI in 2022, compared to 24% in 2019, as illustrated on a run chart (Figure 1). Patients can complete BASDAI forms sent to them in a previous month, therefore the completion rate some months exceeds 100%. In a dedicated focus group, patients reported that ePROMs were generally more convenient, and provided a useful record to refer back to. This could be further improved by development of a graph function to view scores over-time and the ability for patients to complete a questionnaire between appointments when they feel their disease is more active. A key theme for improving the use of ePROMs was the need for more discussion about their utility and around individual patient’s scores. There is concern that the BASDAI and BASFI scores are arbitrary and lack nuance, and that the importance of these scores at an individual patient level is not clear. This may be rectified by more discussion with clinicians in appointments, to add meaning to these scores. There was also concern that sleep and other generic domains. Relative contraindication to anti TNF drugs, which would not have been considered significant in the past, was the second reason. Efficacy and safety outcomes were comparable to other biologics. This confirms that shared decision

IL-17 OR TNF INHIBITORS - REAL WORLD IMPACT OF SHARED DECISION MAKING IN A NURSE LED BIOLOGICS SERVICE

Keywords: bDMARD, Spondyloarthitis, Real-world evidence

J. Begum1, M. Nisar1, 1Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom

Background: Since the availability of anti TNF biosimilars and the push from reimbursement panels to use them first line, real world data regarding therapeutic choice in biologic naïve population is sparse.

Objectives: Evaluate the reasons for nurse led service choosing IL17 antagonists in biologic naïve SpA patients, in a shared decision making model, despite the availability of cheaper anti TNF biosimilar.

Methods: We conducted a retrospective analysis of our electronic register for people with PsA and AS from 1994 to 2022 using April 2022 at our university teaching hospital. We had access to full patient records including details on comorbidities, drugs and disease management. All patients were evaluated in biologic naïve population is sparse.

Results: PsA. 90 patients were prescribed Secukinumab since its availability in the UK. Mean age was 51 yrs (24-80) and 56% (62%) were women. All were prescribed since the adoption of Adalimumab biosimilar. Median duration of therapy was 551 days (62-1284). Mean TJC and SJC were 8.14 (1-64) and 3.15 (1-57) at initiation which improved to 6 months to 6.28 (1-46) and 2.77 (1-18) respectively. Contraindications for biologic naïve; 18 had it for better efficacy (six had axial disease, four with enthesitis and eight with concomitant moderate to severe psoriasis) and six for relative anti TNF contraindications including three with treated solid organ neoplasms, one with BMI>35 and two for concurrent chronic infections including HIV. AS. 47 patients were prescribed Secukinumab. Mean age was 54 (27-79) and half were women. Median duration of therapy was 679 days (51-1154). Mean BASDAI was 3.3 (0-9.2) at initiation which improved to 2.1 (0-7.5). 11 (23%) were biologic naïve; five had it for better efficacy and six for relative anti TNF contraindications including three with treated cancers, two with latent TB and one for MS.

Conclusion: To our knowledge this is the first dedicated retrospective review of a large real world spondyloarthritis cohort evaluating reasons for biologic choice. Nearly a quarter of patients were prescribed Secukinumab prior to cheaper adalimumab biosimilar despite it being considered first choice agent in the region. Clinicians including nurse specialists chose it for better efficacy in various SpA domains. Relative contraindication to anti TNF drugs, which would not have been considered significant in the past, was the second reason. Efficacy and safety outcomes were comparable to other biologics. This confirms that shared decision
behaviours and work participation to prevent progression of rheumatic and musculoskeletal diseases.

ADDRESSING AXSPA DIAGNOSTIC DELAY 
BY IMPLEMENTATION OF ASYNCHRONOUS 
TELEMEDICINE AND MEDICAL STUDENT-SUPPORTED 
VISITS

Keywords: Spondyloarthritis, Health services research, Telemedicine

H. Labinsky1,2,3, S. Von Rohr1,3, B. Horstmann1,3, F. Seesse1,3, F. Muehlensiepen1, K. Boy4, M.G. Raimondo2,3, I. Gehring5, J. Rojas- 
Restrepo6, E. Vogt6, A. Ramming6, M. Schmalzing5, G. Schell6, J. Knitza1,2,3. 
1Department of Internal Medicine II, Rheumatology/Clinical Immunology, Würzburg, Germany; 2Friedrich-Alexander-University Erlangen-Nürnberg and Univer-
sitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; 3Friedrich-Alexander-University Erlangen-Nürnberg and Univer-
sitätsklinikum Erlangen, Deutsches Zentrum für Innere Medizin (DZI), 
Erlangen, Germany; 4Brandenburg Medical School Theodor Fontane, Center for 
Health Services Research, Rüdersdorf, Germany; 5Thermo Fisher Scientific, 
Phadia GmbH, Freiburg im Breisgau, Germany

Background: Axial Spondyloarthritis (axSpA) has one of the longest diagnostic 
delays in rheumatology [1]. Teleducational solutions and integration of medical stu-
dents to support routine care may be promising to overcome current limitations 
and accelerate axSpA diagnosis and treatment.

Objectives: We aimed to test a novel diagnostic pathway and asynchronous 
report-based diagnostic assessments for patients with suspected axSpA.

Methods: 40 patients with chronic back pain for more than 3 months completed 
a pre-appointment visit (T-1) with a medical student prior to their planned actual 
first visit (gold standard, T0) (Figure 1). Findings were discussed with a rheuma-
tologist to finalize diagnoses and initiate therapy. Patients also completed two 
digital symptom checkers (SC), started to continuously report ePROs (BASDAI) 
via an app and received upper-arm self-sampling devices to self-collect capillary 
blood at home for remote C-reactive protein (CRP) and HLA-B27 analysis. Two 
additional students and three additional tele-rheumatologists reviewed SC, labo-
 rated and imaging results to investigate an asynchronous telediagnostic approach. 
Acceptance was measured using the net promoter score (NPS) [2]. For this, patients were asked to rate on an 11-point scale ranging from 0 ("Very unlikely") to 10 ("Very likely") how likely they would recommend the applications to 
others. To calculate an overall NPS, the percentage of detractors (rating 0-6) was 
subtracted from the percentage of promoters (rating 9 or 10).

Results: N=36 patients completed the study. AxSpA was confirmed in 17 and ruled 
in 19 cases. The student visit helped to complete diagnostic evaluations prior to 
the actual first visit and the diagnostic delay (T1-T0) was significantly reduced by 
about two months (Med (IQR), 55.5 (67.3) days, p <0.0001). The diagnostic accuracy 
(DA, axSpA yes or no) for the two SC Ada and bechterew-check was 58% and 47%, 
respectively. The student with patient contact reached a DA of 86%, the mean DA ± 
SD of the students who did not have patient contact (asynchronous decision) was 
75% ± 0%. Results of the three tele-rheumatologists showed a high sensitivity (98% 
± 3%) and diagnostic accuracy (89% ± 3%). Imaging results turned out to be an 
esential part for asynchronous decision making, as they significantly increased the 
sensitivity of the decision of all three physicians. Unsupervised at-home self-collec-
tion of capillary blood was successfully conducted by 80% of the patients. For the 
first time, accuracy of self-sampled HLA-B27 was demonstrated. Patients expressed 
high acceptance regarding the pre-appointment student visit, self-sampling and 
ePRO with NPS of +62%, +36% and +31%, respectively.

Conclusion: To our knowledge, this is the first study exploring the potential 
of self-sampling, medical students and asynchronous assessments to accelerate 
axSpA diagnosis. The investigated elements were well accepted among patients and 
significantly reduced axSpA diagnostic delay.

RESULTS:

Periodic follow-up (FU) is necessary for patients with Rheumatic Diseases (RDs). In the case of a stable clinical condition or low disease activity, FU can be carried out also by rheumatology nurses (RNs). Recent studies focusing on FU led by RNs either in Rheumatology Clinics and with Teleunening (TN), showed promising results in terms of outcomes, cost reduction and users’ satisfaction.

Objectives: To evaluate the feasibility of a Teleunening FU in a Rheumatology Centre in Florence, Italy.

Methods: In this pilot study, patients with stable inflammatory arthritis or low disease activity were contacted, after their first visit, through TN (T0) and then assessed during the following in-person visit (V12) by RNs for treatment adherence, for pain, for mental and physical health, for workability, for perception of disease activity and satisfaction concerning the TN service.

Results: Out of 27 interviewed patients, 59.3% (n=16/27) was affected by Rheumatoid Arthritis (RA), 18.5% (n=5/27) by Spondyloarthritis (AS), 14.8% (n=4/27) by Psoriatic Arthritis (PsA) and 74% (n=20/27) by Juvenile Idiopathic Arthritis. The mean age was 57±5.13 (Ms: DS) years and the treatment adherence level was optimal. 11.1% (n=3/27) of patients was referred for medical consultation because of the urgent clinical situation assessed by the RNs according to the clinical multidisciplinary checklist. After specialist consultation, 1 patient was redirected to urgent dermatology consultation because of a suspected cutaneous drug reaction. During the TN period (12 months), 33.3% (n=9/27) of the patients contracted SARS-CoV-2 infection and 11.1% (n=3/27) contracted urinary or upper respiratory tract infections. RA patients showed a mean Psoriatic Arthritis Impact of Disease-RAID score of 2.4 at T0 and 2.5 at V12 (Range 0-10): AS patients showed a mean Assessment of Spondyloarthritis International Society-ASAS score of 0.3 in both periods and PsA showed a mean Psoriatic Arthritis Impact of Disease-PSAID score of 0.7 and 0.8 at T0 and V12, respectively. Among RA, AS and PsA patients, as a pain score of 3 was recorded in both periods. In order to attend the in-person FU visit, 68.4% (n=13/19) of the patients took work leave. 37% (n=10/27) of them waited 40.9±18.6 minutes at V12 control. The average distance between the Rheumatology Centre and patients’ home was 29.3±25.6 km. 15.4% (n=5/33) of the respondents did not own a car and 23.1% (n=3/13) was accompanied to visit their caregiver. All the included patients expressed high satisfaction for the TN service, corresponding to 5 point Likert scale.

Conclusion: The data show that TN FU is a valuable model for maintaining an adequate level of therapeutic adherence, reducing the travel time and working day loss, intercepting remotely clinical issues, as well as registering a high level of user acceptance and satisfaction. Further studies on larger samples are needed to confirm our findings.

Results: A total of 7715 teleconsultations were eligible for analysis after excluding 39 cases with incomplete data. The most frequent diagnostic hypotheses generated during teleconsultations were rheumatoid arthritis (RA), non-specific arthralgia/arthrosis, and systemic lupus erythematosus (Table 1). Fibromyalgia, gout, and osteoarthritis were other diagnostic hypotheses commonly considered. Almost one-third (n=2219; 29% of total consultations) of the discussions referred to patients already waiting for rheumatology consultation, and teleconsulting replaced the in-person specialist evaluation in 32% (n=722) of these cases. Of the 5496 that were not waitlisted, 1369 (24.9%) were referred after teleconsulting. In total, 54.9% of the teleconsultations decided that the patients could be adequately managed in the PHC. The Figure 1 describes the utilization pattern of the rheumatology teleconsulting service during the time frame of this study. The utilization of the teleconsulting service increased significantly, and the proportion of patients referred to in-person rheumatology consultations reduced over the last years (P<0.001).

Figure 1.

Conclusion: Prevalent rheumatic diseases, especially RA, are frequent reasons for using teleconsulting support in our country. According to our study, after guidance, the PHC physician was considered able to manage most cases in rheumatology. This reduced the waiting list by approximately one-third. There was a progressive increase in teleconsultations over the years, but the proportion of patients referred to rheumatology reduced over time.

POS1205-HPR PRESCRIBING TRENDS OF METHOTREXATE IN RHEUMATOID ARTHRITIS: A TUNISIAN SURVEY

Keywords: Disease-modifying drug (DMARDs), Rheumatoid arthritis

F. Alia1, O. Hamdi1, S. Miladi1, M. Yasmine1, H. Boussaa1, L. Souebni1, K. Ouniche1, S. Chekili1, S. Kassab1, K. Ben Abdelghani1, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia

Background: Methotrexate (MTX) remains the first line disease modifying anti-rheumatic drug (DMARD) in the course of treatment for rheumatoid arthritis (RA). There are wide variations in prescribing pattern among rheumatologists.

Objectives: We aimed to determine the prescribing practices of MTX by Tunisian rheumatologists.

Methods: We conducted a cross-sectional study including Tunisian rheumatologists. An online survey composed of 18 questions via Google Drive Forms was designed to analyse the prescription trends of MTX in RA patients.

Results: The online questionnaire was sent to 184 rheumatologists, 66 of whom (35.8%) responded. The majority of rheumatologists initiated MTX at therapeutic doses: 10 mg/week (34.8%) and 15 mg/week (36.3%). Ninety-eight percent of rheumatologists preferred the oral route during the initiation of MTX. Fifty-nine percent of rheumatologists advised their patients to take MTX on an empty stomach. Doctors preferred injectable MTX in case of digestive intolerance (96.9%) or in case of lack of efficacy (48.4%). Regarding the MTX escalation strategy, the majority of rheumatologists followed a conventional strategy with an increase in doses in steps of 2.5 mg (65%) and 5 mg (35%) every 02 (16.6%) to 04 (42.4%) weeks. The optimal dosage of MTX was reached after 08 and 12 weeks in 27.2% and 59% of cases, respectively. Sixty-eight percent of rheumatologists split doses of MTX, 60% of whom from a dose of 15 mg/week. The time interval between the two doses was 06 (27.2%) to 12 hours (27.2%). All rheumatologists systematically associated folic acid with MTX. The average dose of folic acid prescribed was 10 mg/week (72.7%). The doctors questioned advised patients to take acid folic 48 hours after MTX 51.5%. The maximum dose of MTX prescribed by rheumatologists before switching to biological (b) DMARDs was 20 mg/week (60.6%). In case of use of bDMARDs, 63.6% of doctors decreased the dose of MTX to 10 mg/week. Once remission is reached, 34.8% of doctors continued MTX at the same dose while 62% of them gradually reduced the dose (decrease of 2.5 mg every 02 weeks in 27.2% of cases and 5 mg every 08 weeks in 34.8% of cases).

Conclusion: Our study showed that the majority of Tunisian rheumatologists prescribe MTX according to international recommendations. Indeed, the current therapeutic strategy for RA encourages powerful and effective treatment early in the course of the disease.

**Background:** Inflammatory myopathies (IM) are autoimmune diseases characterized by muscle inflammation and weakness. Damage is a prognostic factor in IM, but its assessment in daily clinical practice represents an unmet need. In other settings than IM, a low muscle mass and strength (referred as sarcopenia) have been linked with disability, decreased quality of life and increased mortality. Sarcopenia has never been studied in IM.  

**Objectives:** To determine the prevalence and clinical significance of low muscle mass, strength and sarcopenia in inactive or low-activity IM.  

**Methods:** Adult IM patients according to 2017 ACR/EULAR classification criteria with disease duration ≤12 months, creatine kinase (CK) serum level ≤500 U/l, >6-month stable medication and Physician Global Activity ≤3/10 were prospectively evaluated. Physical performance, disability, respiratory volumes and maximum inspiratory (Pimax) and expiratory pressures (Pemax) were assessed. Sarcopenia was diagnosed according to the EWGSOP consensus.1 Several myokines were measured in the blood.  

**Results:** Forty IM patients (27 females, 68%) with an average age of 59.9 years (±14) and 30 healthy age and sex-matched volunteers (19 females, 63%) were prospectively enrolled. Eight patients suffered from dermatomyositis (DM); twelve from immune-mediated necrotizing myopathy (IMNM); eleven from anti-synthetase syndrome (ASS), nine from scleromyositis (SM) since 4.6 years (2.9–8.4). At the enrolment, MMT-W was 140/150 (135.3–147), MMT-12 was 212/203 (203.3–216.8), CK were 122 U/l (87.5–195.5), ALM correlated with MMT-W (r=0.4, p=0.01), MMT-12 (r=0.5, p=0.004), grip strength (r=0.5, p=0.005), 6-minute walking distance (6MDW) (r=0.6, p=0.0002), time to drink a 20 centilitre cup (r=0.5, p=0.001), vital capacity (r=0.5, p=0.02), Pimax (r=0.6, p=0.003) and Pemax (r=0.6, p=0.004), severity (r=0.5, p=0.003), extension (r=0.4, p=0.007) and global (r=0.6, p=0.0001) damage. Grip strength correlated with MMT-W (r=0.5, p=0.003), MMT-12 (r=0.4, p=0.005), ALM (r=0.3, p=0.05), 6MDW (r=0.4, p=0.02), global damage (r=0.4, p=0.008), HAQ score (r=0.3, p=0.04). Seven out of forty myositis patients (17.5%) were sarcopenic (vs 0% in the control group). They suffered from IMNM (57% vs 24%), DM (29% vs 18%) and SM (14% vs 24%). No patient suffered from ASS (0% vs 33%). Sarcopenic patients had history of severe muscle involvement: loss of walking ability (vs 21%, p=0.0002), higher maximum CK values (5998 U/l (3488-6500) vs 1636 (626-5000), p=0.07), respiratory muscles impairment (29% vs 3%, p=0.02) and myocarditis (43% vs 3%, p=0.001); and they more frequently required intravenous immunoglobulins (86% vs 33%, p=0.03), plasmapheresis (29% vs 3%, p=0.02) and/or unconventional immunosuppressants (57% vs 27%, p=0.01). By contrast, extramuscular involvements were less frequent (43% vs 76%, p=0.08). None of sarcopenic patients had inflammatory joint involvement during the follow-up (0% vs 49%, p=0.02). At the time of evaluation, sarcopenic patients had lower MMT-W (131/150 vs 142/150, p=0.004) and MMT-12: 199/220 vs 215/220, p=0.004), reduced 6MDW (196 (180) vs 478 (487) meters, p<0.0001) and HAQ score (2.1 (1.2-2.8) vs 0.6 (0.3-1), p=0.0008).  

**Conclusions:** Sarcopenia is associated with severe damage in myositis patients, being identified as a prognostic marker in the management of these patients.
INCIDENCE, PREVALENCE & MORTALITY IN IDIOPATHIC INFLAMMATORY MYOPATHIES & ASSOCIATED INTERSTITIAL LUNG DISEASE IN ENGLAND: A NATIONAL COHORT USING ROUTINELY COLLECTED ADMINISTRATIVE DATA

1King’s College Hospitals NHS Trust, Department of Rheumatology, London, United Kingdom; 2King’s College London, Department of Academic Rheumatology, London, United Kingdom; 3National Disease Registration Service, NHS Digital, National Congenital Anomaly and Rare Disease Registration Service, United Kingdom; 4School of Medicine, University of Nottingham, Department of Lifespan and Population Health, Nottingham, United Kingdom; 5Nottingham University Hospitals NHS Trust, Department of Rheumatology, Nottingham, United Kingdom; 6National Disease Registration Service, NHS Digital, National Cancer Registration and Analysis Service, United Kingdom

Background: Ethnicity, sex, age & socioeconomic deprivation can all lead to health inequity. Impact of these factors in epidemiology of Idiopathic Inflammatory Myopathies (IIM) has not been widely researched.

Conclusion: In collaboration with National Congenital Anomaly & Rare Disease Registration Service (INCARDRS), we described national incidence, prevalence & mortality in IIM and associated Interstitial Lung Disease (IIM-ILD) according to demographics.

Methods: Hospital Episode Statistics (HES) collected at every NHS hospital admission in England, were used to create a national cohort of patients with IIM & IIM-ILD associated ICD-10 codes between 2006-2022. Cases were identified using pre-validated methods [1]. Sex, ethnicity, Index of Multiple Deprivation (IMD) and death certification were collated. Denominator populations were extracted from Office of National Statistics publications. Incidence rates were calculated by multivariate Poisson regression, standardized mortality ratio (SMR) by indirect standardization, and survival analysis by multivariate Cox models. Incidence Rate Ratios (IRR) were mutually adjusted for age, sex & IMD Ethnicity (IRR was not adjusted for IMD due to lack of suitable denominator data).

Cox models were adjusted for age, sex, ethnicity, IMD and ILD status.

Results: 14,891 incident IIM cases were identified giving an incidence rate of 1.72/100,000 person-years. Point prevalence was 17.9/100,000 in 2022. Mean age was 59.7 years with incidence peaking at 70-80 years. Multivariate models (Table 1) showed IIM incidence was higher in females IRR 1.30 (95% CI 1.25, 1.34), but mortality was lower (hazard ratio (HR) 0.78 (95% CI 0.74, 0.82)). Incidence was higher in Asian and Black ethnicities than White (IRR 1.56 and 2.77 respectively). Mortality was higher in White ethnicity (Asian HR 0.80 and Black HR 0.78). The most deprived population quintile had similar incidence IRR 1.06 (95% CI 1.02, 1.11), but higher mortality HR 1.34 (95% CI 1.25, 1.44) than less deprived populations. 172% of IIM cases had ILD. Incidence of IIM-ILD did not vary largely by socioeconomic deprivation, but incidence was substantially higher in Black, Other and Asian populations compared to White (IRR 5.11, 4.07, 2.48). Mortality of IIM-ILD was also lower in Asian HR 0.76 (95% CI 0.61, 0.95) and Black HR 0.73 (95% CI 0.57, 0.93) patients. SMR was 5.13 for IIM and 792 for IIM-ILD. Crude mortality increases with age, but standardized mortality is highest in younger patients with ILD. (Graph). Death certification was available in 7159 cases. IIM was recognized as a contributory factor in 39%, and ILD in 10.6%. Malignancy was the most reported ‘underlying cause of death’ (24.7%), then cardiovascular disease (19.9%) and respiratory disease (15.8%). Asian and Black ethnicities were less likely to have malignancy mentioned on death certificates (IRR 0.48 and 0.61 respectively).

Figure 1. Standardised Mortality Ratio for IIM and IIM-ILD by Age

Conclusion: We have defined national incidence, prevalence and SMR estimates for IIM and IIM-ILD. Incidence is higher in females, Black, Asian and Other ethnicities. Mortality is higher in White ethnicities, increased deprivation and males. Increased mortality in White ethnicities may partially relate to increased malignancy-associated disease.

INTERNET-BASED ENROLLMENT OF A MYOSITIS PATIENT COHORT

Keywords: Telemedicine, Myositis

1UPMC Internal Medicine/Pediatrics Residency Training Program, Internal Medicine, Pittsburgh, United States of America; 2University of Pittsburgh Rheumatology, Pittsburgh, United States of America; 3Bnai Zion Medical Center, Boston, Massachusetts, United States of America; 4Division of Rheumatology, Haifa, Israel

Background: Recruitment for myositis clinical research is challenging, due to the rarity of the disease and geographic considerations. Remote enrollment using digital health technologies, social media, and tele-medicine provide researchers with more optimal recruitment options. (1)

Objectives: To assess the effectiveness of various remote recruitment strategies in myositis patients.

Methods: "Myositis Patient Centered Tele-Research" (MyPacer) is an NIH-funded multi-center observational study assessing the feasibility, efficiency and acceptability of virtual research in myositis. Subjects were recruited from anywhere in the United States (U.S.) via online strategies: a) Patient organizations (e.g. The Myositis Association [TMA], Myositis Support and Understanding [MSU], etc.) posted a study link on their website, emailed members, and posted on social media; b) Targeted advertisements were posted on Google, Facebook and Twitter; c) Myositis physicians were emailed with a request to refer patients. Interested subjects reviewed study details, e-consented and enrolled via the study mobile application (app) or website. Adult patients who fulfilled self-reported eligibility criteria were enrolled (after physician verification of polymyositis [PM], necrotizing myositis [NM], or dermatomyositis [DM] and fulfillment of at least 4/6 disease criteria for PM/NM, or 3/6 for DM). Disease criteria included: muscle weakness, elevated CK, compatible EMG or biopsy (muscle or skin), DM rash, or a positive myositis associated-auto-antibody. The diagnosis and disease criteria were confirmed by a physician via chart review.

Results: In 6 months, 94 participants were enrolled [71 (75.5%) females, median age of 54 years (SD +/- 13.9), and 76 (80.9%) White, 9 (9.6%) Black, and 3 (3.2%) Asian]. The most common diagnosis was DM (46, 48.9%), then PM (35, 36.2%), NM (7, 7.5%), and unspecified myositis (6, 6.4%). Primary myositis doctors were rheumatologists (80, 85.1%), neurologists (10, 10.6%), or dermatologists (2, 2.1%). We enrolled subjects from 30 states and 5 regions in the U.S., with higher participation from Virginia (n=13; 13.8%), Pennsylvania (n=11; 11.7%), Florida (n=8;8.5%), and California (n=7; 7.4%). Among the main recruitment sources, TMA was responsible for 63 (67%) participants, MSU for 20 (21.3%), and doctor referral for 9 (9.6%). Other recruitment sources (n=53; 56.4%) included 18 (19.1%) via Facebook, 6 (6.4%) via study website, 2 (2.1%) via Twitter, and 1 (1%) via Google advertisements. Participants recruited via Facebook were younger than those recruited via email (mean ages 47.39, SD +/- 10.66 and 56.59, SD +/- 13.63 respectively; 95% CI 2.15-16.25; p=0.01). For enrollment method, 62 (66%) individuals used the study app, and 32 (34%) used the study website. The app was the preferred method throughout the country, except in the Southeast where 51.7% of participants used the study website. The mean age of app and website users was 51.79 (SD +/- 12.43) and 60.12 (SD +/- 14.23) years, respectively (95% CI 2.68-13.98; p=0.004).

Conclusion: Online recruitment is a viable alternative for maximizing potential recruitment in myositis clinical studies. We remotely enrolled patients from every region in the U.S. Patient support organizations were very successful in augmenting recruitment. Moreover, Facebook was responsible for almost 20% of participants, especially within the younger (ages 30 to 66) population. Our study app appeared quite functional with 66% use of the enrolled subjects and a clear favorite in younger individuals compared to website use. We hope these findings will guide future online myositis studies and advance clinical research.

PATIENTS WITH SUBCLINICAL HEART INVOLVEMENT AT DIAGNOSIS OF MYOSITIS ARE MORE LIKELY TO PRESENT CARDIOVASCULAR EVENTS THAN PATIENTS WITHOUT CARDIAC INVOLVEMENT IN A MONOCENTRIC RETROSPECTIVE STUDY

Keywords: Heart, Myositis

C. Kasser1, A. F. Guedon1, A. Mekinian1.
1Hospital Saint-Antoine Ap-Hp, Internal Medicine, Paris, France

Background: Idiopathic inflammatory myositis (IM) is a group of rare and heterogeneous systemic diseases characterized by clinical muscle weakness and histological inflammation in skeletal muscles. Myositis classification distinguishes dermatomyositis (DM), inclusion body myositis (IBM), immune-mediated necrotizing myopathy (IMNM), anti-synthetase syndrome (ASSD) and overlap myositis (OM) [1-2]. Patients with myositis are more likely to die younger than in general population [3]. Cardiovascular events (CVE) are one of the main causes of death during the disease's course [4].

Objectives: To investigate the occurrence of CVE and their link with features of cardiac involvement in a French myositis population.

Methods: We conducted a retrospective observational cohort study of patients with a diagnosis of DM, ASSD, IBM, IMNM or OM, from the department of internal medicine in Saint Antoine's hospital, Paris, France, between 1992 and 2020. Demographic and clinical data were collected at diagnosis, at the last follow up visit, and at the first CVE if one happened. Subclinical heart involvement was defined by electrocardiogram abnormality, transho- racic echocardiography abnormality or cardiac MRI abnormality. CVE were defined by the occurrence during the follow up of heart failure, inflammatory myocarditis or admission in resuscitation department. Descriptive, bivariate and survival analysis were performed.

Results: Among the 78 patients included, 52 (67%) were women. Thirty three patients (42%) had a DM, 18 (23%) an ASSD, 12 (15%) an OM, 11 (14%) an IMNM and 4 patients (5%) an IBM. Mean age at diagnosis was 49 years. Median follow up time was 72 months. Subclinical involvement was present at diagnosis for 17 (22%) patients; and 14 (21%) patients presented a CVE during the follow up period. Patients with subclinical cardiac involvement at diagnosis were more likely to present a CVE than patients without subclinical cardiac involvement. Three years after the diagnosis, 7 CVE occurred in the subclinical cardiac involvement group (event rate 37.5%, 95% CI 4.92-58.92) and only 1 CVE occurred in the no cardiac involvement group (event rate 1.89%, 95% CI 0-5.48). Time to CVE was significantly different between groups (log rank test p < 0.001, Graph 1). This difference remains significant at 5 years after myositis diagnosis.

Conclusion: Patients with subclinical cardiac involvement at myositis diagnosis are more likely to present CVE in the first 5 years of disease than patients without subclinical cardiac involvement. Clinical cardiac involvement is rare at diagnostic, but subclinical cardiac involvement seems to be a more frequent condition. Our results suggest that we should pay more attention to patient with subclinical cardiac involvement at myositis diagnosis, especially in the first years of the disease’s course.

Figure 1.
Background: Polyomysitis (PM) and dermatomyositis (DM) are autoimmune systemic diseases characterized by muscle weakness and inflammatory cell infiltration into skeletal muscle. Myocardial involvement is a common cause of death in PM/DM. It has been reported that myocardial involvement is observed in 9% to 72% of PM/DM [1], but it is still unclear. Electrocardiogram (ECG) and echocardiography are the most often used tests to evaluate cardiac abnormalities, but early detection of myocardial involvement in PM/DM is difficult. Cardiac magnetic resonance (CMR) is a noninvasive technique that has been efficiently evaluated for the evaluation of myocardial fibrosis and scar [6]. T2 mapping is used for the evaluation of myocardial edema. T1, T2 and extracellular volume (ECV) are also analyzed.

Methods: Patients satisfying 2017 ACR-EULAR classification criteria for IIM were prospectively enrolled. All patients underwent thigh MRI (t-MRI) STIR and T2 weighted sequences (axial and coronal) at baseline, 3 and 6 months and DXA scan at baseline and 6 months. Manual muscle testing-8 (MMT-8), Functional index-3 (FI-3), 2-minute walk distance (2MWD) were assessed at baseline, 3 and 6 months. t-MRI was scored using a semi-quantitative score for muscle edema, fascial edema, muscle atrophy and fatty infiltration. Friedman test was used to compare variables at baseline, 3 and 6 months and Spearman correlation was done for agreement of MRI and DXA scores at each other and clinical outcome measures.

Results: Twelve patients (3 patients with PM and 9 patients with DM) were enrolled and all of them completed 6 months follow-up. Median (IQR) age was 38 (27-46) years, disease duration was 6 (2-24). The study group comprised of 10 dermatomysitis, 5 antisynthetase syndrome and 3 immune mediated necrotizing myopathy patients. MRI assessed muscle edema and fascial edema decreased significantly (p<0.01) and fatty infiltration increased significantly (p =0.001) from baseline to 3 months. Muscle atrophy did not change significantly from baseline to 3 months whereas FI-3 continued to improve till 6 months (p=0.000) (Table 1). At baseline MMT-8 (R=-0.631; p<0.01), FI-3(R=-0.689; p<0.01) and 2MWD (R=-0.485; p<0.05) negatively correlated with only muscle edema. At 3 months MMT-8 and 2MWD (R1, R2) negatively correlated with muscle edema (R1=-0.673, R2=-0.591), atrophy (R1=-0.732, R2=-0.577) and fatty infiltration (R1=-0.575, R2=-0.743; p<0.05). FI-3 negatively correlated with only atrophy (R= -0.486; p<0.05). MRI fatty infiltration score and atrophy score did not correlate with DXA assessed leg fat percentage and appendicular mass/ht2 respectively at baseline but had significant correlation (p<0.05) at 6 months (Figure 1).

Conclusion: In IIM, edema decreased and muscle strength increased significantly in first 3 months but fatty infiltration increased. DXA assessment of fat and lean mass did not agree with MRI atrophy and fatty infiltration at baseline probably due to concomitant muscle edema.

Background: Results: Conclusion: Our results propose that myocardial involvement is more likely to develop in PM/DM patients even if the finding of echocardiography is normal. In addition, CMR should be performed in cases of PM/DM with high myoglobin levels, considering the possibility of myocardial involvement.

Negi3. 1Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology and Rheumatology, Puducherry, India; 2Jawaharlal Institute of Postgraduate Medical Education and Research, Radiology, Puducherry, India; 3All India Institute of Medical Sciences, Executive Director, Bilaspur, India

Background: Muscle weakness in inflammatory myopathies (IIM) is due to muscle-edema, atrophy and fatty-infiltration among which edema is the predominant cause at baseline. Some IIM patients donot achieve full muscle power even with immunosuppressive treatment which mainly targets edema. Serial changes occurring in skeletal muscle mass visualized on thigh MRI can help understand the failure of complete recovery. Role of Dual energy X-ray Absorptiometry (DXA) assessed skeletal muscle composition as outcome measure in IIM was not studied previously.

Objectives: To see the changes in skeletal muscle composition over 6 months in IIM patients using imaging and to assess the agreement of MRI and DXA scores with each other and with clinical outcome measures.

Methods: Patients satisfying 2017 ACR-EULAR classification criteria for IIM were prospectively enrolled. All patients underwent thigh MRI(t-MRI) STIR and T1 weighted sequences (axial and coronal) at baseline, 3 and 6 months and DXA scan at baseline and 6 months. Manual muscle testing-8 (MMT-8), Functional index-3 (FI-3), 2-minute walk distance (2MWD) were assessed at baseline, 3 and 6 months. t-MRI was scored using a semi-quantitative score for muscle edema, fascial edema, muscle atrophy and fatty infiltration. Friedman test was used to compare variables at baseline, 3 and 6 months and Spearman correlation was done for agreement of MRI and DXA scores with each other and clinical outcome measures.

Results: 17 patients (12 females) were enrolled and all of them completed 3 months follow-up while only 13 completed 6 months follow-up. Median (IQR) age was 38 (27-46) years, disease duration was 6 (2-24). The study group comprised of 10 dermatomysitis, 5 antisynthetase syndrome and 3 immune mediated necrotizing myopathy patients. MRI assessed muscle edema and fascial edema decreased significantly (p<0.01) and fatty infiltration increased significantly (p =0.001) from baseline to 3 months. Muscle atrophy did not change significantly from baseline to 3 months and 6 months. DXA assessed appendicular lean mass/ht2(p=0.007) and total lean mass/ht2(p=0.021) improved significantly from baseline to 3 months and 6 months. Improvement in MMT-8 and 2MWD was significant only from baseline to 6 months. Improvement in MMT-8 and 2MWD was significant only from baseline to 6 months (p=0.000) whereas FI-3 continued to improve till 6 months (p=0.000) (Table 1). At baseline MMT-8 (R=-0.631; p<0.01), FI-3 (R=-0.689; p<0.01) and 2MWD (R=-0.485; p<0.05) negatively correlated with only muscle edema. At 3 months MMT-8 and 2MWD (R1, R2) negatively correlated with muscle edema (R1=-0.673, R2=-0.591), atrophy (R1=-0.732, R2=-0.577) and fatty infiltration (R1=-0.575, R2=-0.743; p<0.05). FI-3 negatively correlated with only atrophy (R= -0.486; p<0.05). MRI fatty infiltration score and atrophy score did not correlate with DXA assessed leg fat percentage and appendicular mass/ht2 respectively at baseline but had significant correlation (p<0.05) at 6 months (Figure 1).

Conclusion: In IIM, edema decreased and muscle strength increased significantly in first 3 months but fatty infiltration increased. DXA assessment of fat and lean mass did not agree with MRI atrophy and fatty infiltration at baseline probably due to concomitant muscle edema.
Table 1: Serial change in t-MRI scores, DXA assessed lean mass and clinical outcome measures

**Risk of Atherosclerosis-Related Diseases in Adults with Polymyositis and Dermatomyositis: A Large Scale Population-Based Study**

**Keywords:** Myositis

L. Fish1, N. Ben-Shabat2, O. Gendelman3, K. Shari1,2, S. Ehrenberg1, U. Shani1, Y. S. Pat4, A. Watad5, H. Amital1, T. el-Hashomer, Department of Gastroenterology, Ramat Gan, Israel.

**Background:** Select systemic autoimmune diseases show a predilection to Atherosclerotic and Cardiovascular Disease (ASCVD) largely attributed to proinflammatory cytokines supporting the role of the inflammatory hypothesis in endothelial dysfunction and subsequent clinical sequel. Dermatomyositis (DM) and polymyositis (PM) are polygenic autoimmune disorders involving mainly skeletal muscles. The association between DM/PM and ASCVD has not been well addressed and explored.

**Objectives:** To investigate the association between DM/PM and ASCVD events by exploring incidence, mortality, and interaction with respect to disease-modifying agents, autoantibodies, and traditional CVD risk factors in a large, population-based sample.

**Methods:** A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All DM and PM patients diagnosed between 2000-2016 were included with age- and sex-matched controls in a 1:5 ratio. Follow-up continued until the first diagnosis of ASCVD or death. The incidence of ASCVD was compared between the groups using univariate and multivariate models adjusting for baseline cardiovascular risk factors.

**Results:** The study population included 1,567 DM/PM patients and 7,676 controls. The mean age at the index date was 32.5 years (SD±19 years), and the female proportion was 60.3%, similar for both groups. Traditional cardiovascular risk factors were similar between both groups. Median follow-up time was 8.4 (3.6-12.8) in the PM/DM group compared to 8.6 (3.7-12.9) in the control group. 47 (3.0%) PM/DM patients were diagnosed with IHD compared to 140 (1.8%) controls, yielding an Unadjusted HR of 1.66 (1.19 to 2.30). Unadjusted HR for CVA in the PM/DM group was (95%CI) 2.17 (1.86 to 4.11). Unadjusted HR for ASCVD (95%CI) was 1.88 (1.46 to 2.43). APLA-associated antibody predicted ASCVD among PM/DM groups as compared to non-ASCVD PM and DM patients (OR- 2.33, 95% CI - 1 to 4.86; p=0.0001).

**Conclusion:** Our study demonstrates that PM and DM are both associated with an increased risk of MI and ischemic stroke. Furthermore, PM and DM patients positive for APLA-associated antibodies were associated with excessive rates of ASCVD. Taken together, these findings support the increased need for awareness and surveillance of cardiovascular outcomes in the DM/PM cohort.

**Patient Reported Outcome for Physical Function in Idiopathic Inflammatory Myopathy**

**Keywords:** Patient reported outcomes, Myositis

S. Kure1, R. Lomanto Silva2, A. Sharma3, T. Chandra4, S. Moghadam-Kia5, C. V. Oddis6, R. Aggarwal1, B. Iznar Zion Medical Center, Rheumatology, Haifa, Israel; 2University of Pittsburgh Medical Center, Internal Medicine, Pittsburgh, United States of America; 3University of Pittsburgh Medical Center Mercy, Internal Medicine, Pittsburgh, United States of America; 4Medstar Georgetown University Hospital, Rheumatology, Washington DC, United States of America; 5University of Pittsburgh Medical Center Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America

**Background:** Patient-reported outcomes (PRO) measures provide direct and valuable information on treatment efficacy and quality of life. However, the commonly-used PRO measures in idiopathic inflammatory myopathies (IIM) have several psychometric limitations. The Patient-Reported Outcomes Measurement Information System (PROMIS) is an NIH initiative, with several PROs developed and validated in different medical conditions.

**Objectives:** To (1) investigate the psychometric properties of PROMIS physical function-20 (PF-20) in a large US-wide IIM population, and (2) evaluate the feasibility and compliance of PRO measures administered in a local clinic compared to remote US-wide patients.

**Methods:** "Myositis Patient Centered Tele-Research" (My PACER) is a multi-center prospective 6-month observational study of U.S. IIM subjects, competitively recruited through traditional in-person clinic visits (Center-Based Cohort [CBC]), and remotely using smartphone technology, wearable devices, and
telerehabilitation principles (Tele-Research Cohort [TRC]). Data collection included baseline demographic and clinical parameters, PROM and other patient self-assessments at 6 monthly visits, including myositis core set measures (health assessment questionnaire [HAQ-DI], patient global disease activity), PROMIS PF-20, functional tests (six-minute walk, timed up-and-go [TUG] and sit-to-stand [STS] tests), and physical activity monitor. Physician-reported assessments including myositis core set measures (manual muscle testing [MMT], physician global disease activity, extra-muscular global disease activity, creatine kinase [CK]) were obtained at baseline and 6 months.

Results: 141 IIM patients were enrolled (94 TRC/47 CBC). Mean age was 55±13.4 years, female sex 106/141 (75.2%), and 113/141 (80.1%) Caucasians, with similar demographics between the two groups. 116 patients completed the PROMIS-PF form (79 [84%] and 37 [78.7%] in TRC vs. CBC group) with a mean of 6.6±1.7 vs. 6.3±1.5 times per patient (p=0.33) in TRC and CBC group, respectively. The PROMIS PF-20 score was not associated with age, gender, or race. There was no difference between the mean PROMIS PF-20 score in the TRC and CBC groups (p=0.84). The mean PROMIS PF-20 score was 43.9 ± 9.5 in the whole cohort, with 26/116 (22.4%) with a mean t-score lower than 35, indicating severe functional limitation, which was similar between TRC and CBC groups. PROMIS PF-20 showed strong test-retest reliability with a high correlation when repeated at 1 month (r=0.94, p<0.0001). At baseline, PROMIS PF-20 was significantly associated with all core set measures except extra-muscular global and CK. In addition, PROMIS PF-20 was associated with myositis symptoms as well as functional tests and physical activity (Table 1), indicating good validity. Finally, absolute changes in the PROMIS-PF t-score (between the baseline and 6-month visit) were significantly associated with changes in some of the core set measures as well as with the STS and physical activity.

Conclusion: PROMIS PF-20 demonstrates favorable psychometric properties in a large cohort of myositis patients, with similar compliance and results in patients recruited traditionally from clinics or remotely using social media and digital health technology.

Background: Viral infections are known triggers of disease flares in idiopathic inflammatory myopathies (IIMs). Reports of post-COVID-19 flares of IIMs have raised suspicion of a possible role of SARS-COV-2 in their onset [1,2]. However, despite rising flare rates in this vulnerable patient group during the pandemic, the risk factors for post-COVID-19 IIMs flares remain unknown [3,4].

Objectives: Disease flares among patients with idiopathic inflammatory myopathies (IIMs) can lead to significant disability, though are poorly explored in the post-COVID-19 period. We analysed risk factors for post-COVID-19 flares in a global sample of IIM patients in a subset analysis as part of the ongoing COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: A cross-sectional patient self-reporting survey was circulated by the International COVAD study group (157 collaborators, 106 countries) to patients with autoimmune diseases and healthy controls from February-June 2022. Data was collected on demographics, autoimmune disease details, treatment history, comorbidities, COVID-19 history and course and COVID-19 vaccination details. Patients with IIMs who flared post COVID-19 were compared to those who did not using a chi² test. Factors with a significant p value were included in a multivariable analysis considering the most important, up to one of the top 10/12 variables (binary logistic regression using the Enter method) with adjustment for age, gender, ethnicity, vaccine type, immunosuppression, autoimmune and non-autoimmune comorbidities, COVID-19 antibody status, and clinical symptoms of COVID-19. Statistical analyses were performed using IBM SPSS version 28.0, with statistical significance considered at p<0.05.

Results: 15,165 respondents completed the survey of whom 1,169 contracted COVID-19. Of these, 207 had IIMs (median [IQR] age 57.0 [47.0-67.0], 71% female, 74.4% Caucasian). We noted with concern that nearly a third of patients with IIMs (63/207, 30.4%) reported experiencing a flare. A past medical history significant for Asthma, (34.9% vs 6.9%, multivariable OR: 7.1; 95%CI: 3.1-16.4, p<0.001) and specific clinical symptoms during COVID-19 including joint pain (multivariable OR: 6.05; 95%CI: 1.89-22.9, p=0.005), and rate of change in breathing (multivariable OR: 3.43; 95%CI: 1.09-10.8, p=0.036) were found to confer a higher risk of flares (Table 1).

Difficulty in breathing

Conclusion: We observed a high frequency of patients with IIM experiencing post-COVID-19 disease flares. A past history of Asthma and those with certain acute COVID-19 symptoms were at higher risk.

Keywords: Myositis, Mental health, Patient reported outcomes.
Background: Prevalence of comorbidities and their impact on health outcomes in Idiopathic inflammatory myopathies (IIMs) is limited.

Objectives: This study aimed to explore the prevalence of multimorbidity in patients with IIMs, other autoimmune rheumatic diseases (AIRDs) and Healthy controls (HCs). We further explore the impact of comorbidities on patients’ physical, mental, and social health assessed by the Patient-Reported Outcome Measurement Information System (PROMIS) instruments.

Methods: Data for this study were acquired from the COVAD 2 e-survey hosted by a study group consisting of 167 collaborators in 110 countries. Basic multimorbidity (BM) was defined as the co-occurrence of two or more comorbidities in an individual, while complex multimorbidity (CM) signified the co-occurrence of 3 or more chronic conditions affecting 3 or more different organ systems. PROMIS global physical health (PGP), mental health (PGM), fatigue 4a (F4a) and physical function short form (SF10) were analysed using descriptive statistics and linear regression models. Hierarchical Clustering on Principal Components was performed to outline the grouping.

Results: Of 10740 complete respondents, 1558 IIMs, 4591 AIRDs and 3652 HCs were analysed. Individuals with IIMs exhibited higher burden of any comorbidity (OR: 1.62 vs AIRDs and 2.95 vs HCs.p<0.01), BM (OR: 1.66 vs AIRDs and 3.52 vs HCs.p<0.01), CM (OR: 1.69 vs AIRDs and 6.25 vs HCs.p<0.01), and mental health disorders (MHDs) (OR: 1.33 vs AIRDs and 2.63 vs HCs.p<0.01). IIM patients with comorbidities (and MHDs) had worse physical function (low PGP, PGM, SF10 and higher F4a scores, all p<0.01). Worse physical function (PGP) was predicted by age (0.35; 0.030), active disease (-1.51; <0.001), BM (-1.11; <0.001), and MHDs (-1.47; <0.001). PGM was impacted by age (0.51; 0.004), active disease (-1.34; <0.001), BM (-0.75; 0.001) and MHDs (-2.22; <0.001). Determinants of SF10a were age (-3.86; <0.001), active disease (-7.03, <0.001), female (2.85, <0.001), BM (-2.95; <0.001) and MHDs (-2.37; <0.001). Fatigue (F4a) was impacted by age (-0.96, <0.001), active disease (1.45, <0.001), country human development index (0.95; 0.038), BM (1.11; <0.001) and MHDs (2.17; <0.001). Four distinct clusters (Figure 1A, Table 1) were identified i.e., cluster 0: lower burden of comorbidities and good health status; cluster 1: older patients, with higher burden of comorbidities and poor health status, whilst overlap myositis were similarly represented in all clusters, whilst inclusion body myositis and polymyositis were more prevalent in cluster 1 (60.6% and 17.2%) and 3 (32% and 175%), while overlap myositis was more prevalent in cluster 2 (25.6%) and 0 (32.7%) (Figure 1B).

Conclusion: Patients with IIMs have a higher burden of comorbidities that adversely impact physical and mental health, calling for optimized approaches for holistic patient management.

INCIDENCE, FEATURES AND OUTCOME OF DISEASE RELAPSE AFTER COVID-19 VACCINATION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: COVID, Myositis, Vaccination/Immunization

T. G. Béklé,1, M. Nagy-Vincze,1, K. Szabó,1, A. Vincze1, B. Mitényi-Szabó1, Z. Varga1, J. Varga1, Z. Griger1.1University of Debrecen, Division of Clinical Immunology, Faculty of Medicine, Debrecen, Hungary; 2University of Debrecen, Department of Medical Imaging, Division of Nuclear Medicine, Debrecen, Hungary

Background: The approved COVID-19 vaccines showed clear safety and efficacy in reduction of severe SARS-CoV-2 disease. Patients with idiopathic inflammatory myopathies (IIM) were not well represented in these vaccine trials and there are limited data in the literature about development of confirmed disease flare after COVID-19 vaccination.

Objectives: To evaluate frequency, features and outcome of disease relapses in patients with IIM following SARS-CoV-2 vaccination.

Methods: A cohort of 176 IIM patients (mean age: 57.6 years, 117 females, 59 males, 106 PM, 70 DM) were interviewed after the 3rd wave of COVID-19 pandemic and prospectively followed. Relapses were determined using the IMACS disease state criteria, outcome of the flares with myositis response criteria, calculating the total improvement score (TIS).

Results: A total of 146 (82.9%) patients received vaccination and 17/146 (11.6%) patients had relapse within 3 months and 13/146 (8.9%) patients within one month. The relapse rate of unvaccinated patients (1/30; 3.3%) was not significantly different (p=0.1). No fatal flare has been observed. Three months after the post-vaccination relapses, 70.6% of the patients (12/17) achieved improvement of disease activity (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 30±15.81; 7 minor, 5 moderate and 0 major improvement).

Conclusion: Our data show an increased rate of anti-MDA5 positivity in the latter stages of the COVID-19 pandemic, as previously noted in the UK (Hannah J, ACR 2022). Most cases had MDA5 positivity without confirmed autoimmune disease and despite the MDA5 positivity occurrence in the face of the COVID-19 pandemic further longitudinal observation is needed to ascertain any potential links with either infection, vaccination or both.

Conclusion: In this cross-sectional study, 15% of patients with ASyS fulfilled the definition of progressive fibrosis and thus could be eligible for anti-fibrotic treat- ment. To our knowledge, this is the first cohort to demonstrate a possible real-life target of anti-fibrotics in IIM-ILD.

Acknowledgements: NIL.
Method:
We performed a retrospective study of IIM patients followed in a reference center and compared them according to the presence of ILD. Epidemiological, clinical and immunological data, pulmonary function tests (forced vital capacity and diffusing capacity for carbon monoxide), sKL-6 levels and NVC were recollected, if present. Statistical analysis was performed by T-test and Fisher’s exact test to compare qualitative and/or quantitative variables and multiple logistic regression modelling to identify correlation between pulmonary function tests, NVC findings and sKL-6 levels. Values of p<0.05 were considered statistically significant.

Results:
95 patients were included, 47 patients (49%) with ILD. 34% were male with a median age at inclusion of 55.3±24 years and a median disease duration of 6.8±7 years. Avascular areas and capillary loss showed a significant association with the presence of ILD (OR 2.43, 95% CI 1.3-5.7, p 0.004) and (OR 1.7, 95% CI 1.48-3.1, p 0.04). A negative correlation between capillary loss and enlarged capillaries was also found with FVC% (β=-0.46, p<0.001) and DLCO% (β=-0.47, p<0.001) and DLCO% (β=-0.57, p <0.0001) and DLCO% (β=-0.32, p 0.04 and p<0.23, p 0.03), respectively. When we studied the correlation between sKL-6 levels, positive correlations with the presence of ILD (β=0.77, p 0.0004), the presence of hemorrhages (β=0.64, p 0.03) and negative correlations with FVC% (β=-0.47, p 0.001) and DLCO% (β=-0.59, p 0.005) were found. Multiple logistic regression identified as predictors for developing IIM-ILD are summarized in Table 1 and represented in the scatter plot in Figure 1. Male sex, respiratory symptoms, %FVC and %DLCO, sKL-6 levels, anti-Jo1 positivity and the presence of avascular areas and enlarged capillaries in NVC were identified as IIM-ILD predictors (R²=0.974, p =0.006).

Conclusion:
Capillary loss and avascular areas showed a significant association with the presence of ILD, while FVC and DLCO values and sKL-6 levels showed a significant association with the presence of ILD. Avascular areas and capillary loss had a positive correlation with the presence of ILD (OR 2.43, 95% CI 1.3-5.7, p 0.004) and (OR 1.7, 95% CI 1.48-3.1, p 0.04). A negative correlation between capillary loss and enlarged capillaries was also found with FVC% (β=-0.46, p<0.001) and DLCO% (β=-0.47, p<0.001) and DLCO% (β=-0.57, p <0.0001) and DLCO% (β=-0.32, p 0.04 and p<0.23, p 0.03), respectively. When we studied the correlation between sKL-6 levels, positive correlations with the presence of ILD (β=0.77, p 0.0004), the presence of hemorrhages (β=0.64, p 0.03) and negative correlations with FVC% (β=-0.47, p 0.001) and DLCO% (β=-0.59, p 0.005) were found. Multiple logistic regression identified as predictors for developing IIM-ILD are summarized in Table 1 and represented in the scatter plot in Figure 1. Male sex, respiratory symptoms, %FVC and %DLCO, sKL-6 levels, anti-Jo1 positivity and the presence of avascular areas and enlarged capillaries in NVC were identified as IIM-ILD predictors (R²=0.974, p =0.006).

*p<0.05, **p<0.01, ***p<0.001. 1.Erythrocyte sedimentation rate. 2.C-reactive protein. 3. Creatine kinase as ratio of upper limit normal. Mixed models with fixed effect coefficients (b) and 95% confidence intervals (bootstrapped based p-values, 20000 repetitions). All models were adjusted for age and included all available data points.

Objectives: To explore if the patient-reported outcome measure "patient global assessment" (PGA) is associated with markers of inflammation over time and if associations could be explained by functional measures in patients with IIM.

Methods: PGA and inflammatory markers longitudinally collected over 5 years were retrieved for 1333 patients with IIM from the international MyoNet registry. Associations between PGA, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and creatine kinase (CK) were analyzed with mixed effect regression analyses. Mediation analysis was used to test if the associations between PGA and inflammatory markers could be explained by disease-associated symptoms and signs.

Results: PGA improved and inflammatory markers decreased during the first year of observation. High levels of ESR and CRP were associated with worse PGA in both men (ESR:b=0.21, 95%CI 0.10-0.32, p<0.001, CRP:b=0.16, 95%CI 0.04-0.29, p=0.012) and women (ESR:b=0.34, 95%CI 0.25-0.42, p<0.001, CRP:b=0.26, 95%CI 0.14-0.37, p=0.001) across time points, and CK was associated with PGA in women (b=0.70, 95%CI 0.48-0.93 p<0.001) but not in men (b=0.07, 95%CI 0.54-0.68, p=0.831). In men, the association between elevated inflammatory markers and poorer PGA was explained by disability and extra-muscular disease activity whereas in women this association could not be explained by any of the included functional measures. With a few exceptions, the association between reduced inflammatory markers and improved PGA during the first year of observation was partially mediated by improvements in all functional measures.

Conclusion: Higher levels of systemic inflammation were associated with poorer PGA in patients with IIM. In addition to known benefits of lowered inflammation, these findings emphasize the need to reduce systemic inflammation to improve subjective health.

REFERENCES:
Keywords: Myositis, Cardiovascular disease

Methods: 90 patients with IIM (70 females; mean age 56.6; mean disease duration 5.95 years; dermatomyositis: n=29, polymyositis: n=12, immune-mediated necrotizing myopathy (IMNM): n=20, anti-synthetase syndrome: n=29) and 180 HC (130 females, mean age 54.3) were included. In both groups, subjects with a history of CV disease (angina pectoris, myocardial infarction, cerebrovascular and peripheral arterial vascular events) were excluded. Muscle involvement, disease activity, and tissue damage were evaluated by (MMT-8, MITAX, MDI, respectively). Comorbidities and current treatment were recorded. All participants underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (by densitometry (DXA) and bioelectrical impedance analysis (BIA)). The risk of fatal CV events was evaluated by the Systematic Coronary Risk Evaluation (SCORE, charts for the European population) and its modifications: SCORE multiplied by the coefficient 1.5 (mSCORE), and SCORE2.

Results: Compared to HC, IIM patients had a significantly higher prevalence of traditional CV risk factors, cardiac artery disease (CARD), abnormal ABI, and PWV (p<0.05 for all). After propensity score matching (PSM) using traditional CV risk factors, carotid artery disease (CARD), abnormal ABI, and PWV remained associated with increased cardiac risk among IIM subtypes. The calculated CV risk scores by SCORE and SCORE2 (in both IIM and HC), and mSCORE (in IIM only) were reclassified according to CIMT and the presence of carotid plaques. SCORE was demonstrated to be the most inaccurate in predicting CV risk in IIM, while there was a significantly higher proportion of reclassified patients with underestimated CV risk evaluated by SCORE compared to SCORE2 and mSCORE (p<0.02). Age, disease activity, lipid profile, body composition parameters, and blood pressure were the most significant predictors of CV risk in IIM patients (p<0.05 for all variables in bivariate analysis). Moreover, the length of glucocorticoid therapy was positively associated with an increased count of carotid plaques and overall CV risk estimated by US examination (p=0.05 for both).

Conclusion: This cross-sectional cohort study in IIM patients demonstrated a significantly increased risk of subclinical atherosclerosis and CV risk, and also an increased prevalence of traditional CV risk factors compared to HC with comparable age and gender distribution. The most frequent ARS in IIM were the most frequent ARS (39.2%), followed by PL7 (28.8%), PL12 (21.6%), EJ (15.4) and 78.3% southern european caucasians. Sixty three per cent worked in the tertiary sector and 20.5% in the secondary. Some environmental exposition to specific occupational exposure (such as asbestos, coal dust) was found.

Keywords: Myositis, Autoantibodies

Methods: We identified 201 patients with ARS, 125 of them met ASSD criteria. Most were women (62.9%) with a mean age at diagnosis of 59.8 years (DE 15.4) and 78.3% south european caucasians. Sixty three per cent worked in the tertiary sector and 20.5% in the secondary. Some environmental exposition to specific occupational exposure (such as asbestos, coal dust) was found.

Results: We identified 201 patients with ARS, 125 of them met ASSD criteria. Most were women (62.9%) with a mean age at diagnosis of 59.8 years (DE 15.4) and 78.3% south european caucasians. Sixty three per cent worked in the tertiary sector and 20.5% in the secondary. Some environmental exposition to specific occupational exposure (such as asbestos, coal dust) was found.

Conclusion: The estimated cumulative incidence was 1.66 cases per 100,000 inhabitants. Most were women (62.9%) with a mean age at diagnosis of 59.8 years (DE 15.4) and 78.3% south european caucasians. Sixty three per cent worked in the tertiary sector and 20.5% in the secondary. Some environmental exposition to specific occupational exposure (such as asbestos, coal dust) was found.

In the MSA group, 71% (35/49) of patients had TIS response (score ≥20) at week 16, compared to 55% (18/33) in the autoantibody-negative group. In the MSA group 24 patients were randomized to IVIg and of these 83% (20/24) showed TIS response (score ≥20) at week 16 compared to 60% (15/25) in the group of MSA-positive patients receiving placebo. Additional analyses (including results for specific subgroups in the MSA-positive group) will be presented at the EULAR 2023 congress.

**Conclusion:** Myositis-specific antibodies were commonly identified in patients with dermatomyositis in the ProDERM study. Further analyses will determine if specific MSA, such as anti-TIF-1 and others, play a role in treatment response to IVIg.

**Disclosure of Interests:**

All investigators and patients.

**Background:** Idiopathic inflammatory myopathies (IIM) are rare and heterogeneous conditions, associated with cancer in 10 to 30% of cases. While some features have been associated with cancer (age, male sex, dermatomyositis, anti-TIF-1 antibodies), the association with cancer is more debated in antisynthetase syndrome (ASS). Five studies have assessed the prevalence of cancer during ASS meeting the criteria of cancer-associated myopathy (CAM) cancer diagnosed within 3 years before or after the diagnosis of ASS [1].

**Objectives:** The main objective was to assess the prevalence of CAM in patients with ASS. Secondary objectives were to describe clinical features, biological features and prognosis associated with CAM in ASS patients.

**Methods:** In this retrospective multicenter study we included patients of the main tertiary care centers of Grand-Est and Bourgogne-Franche-Comté regions (MyositEst network). Inclusion criteria were age ≥18 years old, and Connors criteria fulfillment. Patients with low antisynthetase antibodies levels were excluded.

**Results:** Among 212 patients screened, 122 patients were included, with a median age of 55.3 ± 14.5 years old, and a female predominance (88%) (Figure 1). The most frequent manifestations of ASS were interstitial lung disease, myositis, skin involvement (81%, 89%, 85% and 57%, respectively), followed by fever and cardiac involvement (16% and 4%, respectively). The most frequent specific antibodies were anti-JO1, anti-PL12 and anti-PL7 antibodies (61%, 17% and 10%, respectively), followed by anti-EJ and anti-OJ antibodies (7% and 16%, respectively). Four patients were positive for both anti-JO1 and anti-PL2 antibodies, and 1 was positive for both anti-JO1 and anti-PL7 antibodies. Among patients included, 15 (12.3%) met CAM criteria. The diagnosis of cancer was made following whole-body imaging (n=10, either CT-scan or 18FDG-poitom emission tomography), systematic cancer screening (n=3) and physical examination (n=2). Patients with cancer were older (63.5 ± 8.27 vs. 52.1 ± 14.7 years-old, p = 0.0001), had lower CPK levels (541 ± 962 vs. 1628 ± 2404 U/L, p = 0.004), less frequently myalgia (20% vs. 46.7%, p = 0.05) and a higher MRC muscle scale (4.93 ± 0.25 vs. 4.6 ± 0.7, p = 0.0014). CAM patients had more frequent history of cancer (46.6% vs. 2.7%, p = 0.004) and had a higher mortality rate (33% vs. 5%, p = 0.003). Age above 55 years-old, fever and CPK below 500 U/L were associated with CAM both on bivariate and multivariate analysis (logistic regression model, entry p value threshold of 0.2, odds ratio > 1.0).

IMPARED HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: A CROSS-SECTIONAL ANALYSIS FROM AN INTERNATIONAL E-SURVEY

Keywords: Patient reported outcomes, Myositis, Quality of life

Objectives: To investigate physical and mental health in a global cohort of IIM patients compared to those with non-IIM autoimmune inflammatory rheumatic diseases (AIIRDs), non-rheumatic AIDs (NRAIDs), and those without AIDs (controls), using Patient-Reported Outcome Measurement Information System (PROMIS) global health data obtained from the COVID-2 survey.

Methods: Demographics, AID diagnoses, comorbidities, disease activity, treat- ments, and PROMS were extracted from the COVID-2 database. The primary outcomes were PROMIS Global Physical Health (GPH) and Global Mental Health (GMH) scores. Secondary outcomes included PROMIS physical func- tion short form-10a (PROMIS PF-10a), pain visual analogue scale (VAS), and PROMIS Fatigue-4a scores. Each outcome was compared between IIMs, non- IIM AIIRDs, NRAIDs, and controls. Factors affecting GPH and GMH scores in IIMs were identified using multivariable regression analysis.

Results: A total of 10,502 complete responses from 1582 IIMs, 4700 non-IIM AIIRDs, 545 NRAIDs, and 3675 controls, which accrued as of May 2022, were analyzed. Patients with IIMs were older [59±14 (IIMs) vs 49±14 (controls)] and more likely to be Caucasian [82.7% (IIMs) vs 53.2% (non-IIM AIIRDs) vs 62.4% (NRAIDs) vs 34.5% (controls), p<0.001]. Among IIMs, dermatomyositis (DM) and juvenile DM were the most common (31.4%), followed by inclusion body myositis (IBM) (24.9%). Patients with IIMs were more likely to have comorbidities [68.1% (IIMs) vs 45.7% (non-IIM AIIRDs) vs 45.1% (NRAIDs) vs 28.3% (controls), p<0.001] including mental disorders [9.7% (IIMs) vs 28.2% (non-IIM AIIRDs) vs 17.9% (NRAIDs) vs 2.9% (controls), p<0.001]. GPH median scores were lower in IIMs compared to NRAIDs or controls [13 (interquartile range 10–15) IIMs vs 13 (11–15) NRAIDs vs 13 (11–15) controls, p<0.001] and PROMIS PF-10a median scores were the lowest in IIMs [34 (25–43) IIMs vs 40 (34–46) non-IIM AIIRDs vs 47 (40–50) NRAIDs vs 49 (45–50) controls, p<0.001]. GMH median scores were lower in AIDs including IIMs compared to controls [13 (10–15) IIMs vs 13 (10–15) NRAIDs vs 15 (13–17) controls, p<0.001]. Pain VM median scores were higher in AIDs compared to controls [3 (1–5) IIMs vs 4 (2–6) non-IIM AIIRDs vs 2 (0–4) NRAIDs vs 0 (0–2)

Sciency Abstracts

controls, p<0.001]. Of note, PROMIS Fatigue-4a median scores were the highest in IIMs [11 (8–14) IIMs vs. 8 (10–14) non-IIM AIDs vs. 9 (7–13) NRAIDs vs. 7 (4–10) controls, p<0.001]. Multivariable regression analysis in IIMs identified older age, male sex, IBM, comorbidities including hypertension and diabetes, active disease, glucocorticoid use, increased pain and fatigue as the independent factors for lower GMH scores. Whereas coexistence of interstitial lung disease, mental disorders including anxiety disorder and depression, active disease, increased pain and fatigue were the independent factors for lower GPH scores. Our results call for greater attention to patient-reported experience and comorbidities including mental disorders to provide targeted approaches and optimise global well-being in patients with IIMs.

**Conclusion:** Both physical and mental health are significantly impaired in patients with IIMs compared to those with non-IIM AIDs or those without AIDs. The complex interactions amongst dysphagia, cancer, and mortality in idiopathic inflammatory myopathies (IIM) have never been studied.

**Methods:** A cohort of adult IIM patients with documented dysphagia exposure within 6 months of disease onset were identified from clinical registries in five countries (Sweden, Canada, Czech Republic, Denmark, and Norway). Mortality rates including 95% CI were calculated. Crude and adjusted mortality rates in IIM patients exposed to dysphagia or not were compared with Kaplan Meier curves and Cox proportional hazard models. To explore possible effect modification of cancer on the association between dysphagia and mortality, an adjusted Cox proportional hazard model stratified on cancer status and including an interaction term between dysphagia and cancer was performed.

**Results:** This study included 230 IIM adult individuals with a mean±SD age at diagnosis of 57±15 years and a mean±SD disease duration of 3±2 months. Of these, 146 (68%) were women. 122 (54%) had severe dysphagia at baseline, 29 (13%) had cancer in the 3 years preceding IIM onset or within 6 months after IIM onset and 112 (49%) had dysphagia. When comparing the subjects unexposed or exposed to dysphagia, interstitial lung disease was more frequent (25 vs 58%), with more dermatomyositis (56 vs 28%) and less anti-synthetase antibody in unexposed or exposed to dysphagia, interstitial lung disease was less frequent (10 vs 36%) in the group exposed to dysphagia. Mortality rates per 100 person-years for IIM patients exposed to dysphagia were 2.3 (95% CI 1.0–4.5) in those without cancer compared to 33.3 (95% CI 16.6–59.2) in those with cancer. Survival curves for dysphagia exposure stratified by cancer status were significantly different (p<0.0001). The main effect of dysphagia exposure in IIM patients without cancer was HR 0.6 (95% CI 0.2–1.8) compared to HR 2.9 (95% CI 0.7–12.4) in those with cancer. Dual exposure to dysphagia and cancer significantly increased the risk of mortality relative to patients with neither condition (p-value interaction 0.05).

**Acknowledgements:** The authors are grateful to all respondents for completing the questionnaire. The authors also thank The Myositis Association, Myositis India, Myositis UK Foundation, the Myositis Global Network, Cure JM, Cure IBM, SJögren's India Foundation, EULAR PARE for their contribution to the dissemination of the survey. Finally, the authors wish to thank all members of the COVAD study group for their invaluable role in the data collection.

**References:**
Conclusion: This is the first study to demonstrate effect modification of cancer on the association between dysphagia and mortality in IIM. This suggests that IIM patients with and without cancer are very different and that separate analyses for the 2 groups should be considered when the outcome of interest is mortality. Reference: None.

POST1233

CLINICAL, SEROLOGICAL AND MUSCLE SHEAR WAVE ELASTOGRAPHY ASSESSMENT IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Ultrasound, Myositis, Imaging

Y. Xin, J. Gao, Y. Li, F. Lu, J. Zhu. Peking University People’s Hospital, Department of Ultrasound, Beijing, China; Peking University People’s Hospital, Rheumatology and Immunology, Beijing, China

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of systemic autoimmune disorders characterized by various degrees of muscle weakness and inflammation. Shear wave elastography may be a potential noninvasive quantitative imaging biomarker.

Objectives: The objective of this work was to describe the demographic, clinical and serological characteristics of IIM patients, and to evaluate the role of shear wave elastography in detecting muscle damage.

Methods: We enrolled 14 patients with IIM fulfilling the EULAR/ACR 2017 criteria and having muscle involvement. Shear wave elastography were performed on rectus femoris (RF), deltoid (DEL), biceps brachii (BB) and sternocleidomastoid (SCM) muscles in these patients and 20 healthy controls along the transverse and longitudinal axes, respectively. Demographic, clinical, and serological characteristics were collected from patients’ medical records.

Results: The study included 14 patients with IIM (5 dermatomyositis, 7 immune-mediated necrotizing myopathy, 2 anti-synthetase syndrome). The mean age at diagnosis was 52.93 (±12.99) years, with 9 females (64.3%). The demographic, clinical, serological characteristics of the patients were summarized in Table 1. Muscle ultrasound of IIM patients revealed increased muscle and fascia echogenicity, indicating obvious edema (Figure 1). The shear wave velocity and dispersion slope of RF (13.9 vs. 16.0 m/s, 6.70 vs. 7.59 kHz/[m/s]; 1.82 vs. 1.95 m/s, 46.12 vs. 47.59 kHz/[m/s]); DEL (1.28 vs. 1.41 m/s, 701 vs. 737 kHz/[m/s]; 2.20 vs. 2.57 m/s, 11.05 vs. 14.39 kHz/[m/s]) and BB (1.29 vs. 1.43 m/s, 712 vs. 754 kHz/[m/s]; 2.28 vs. 2.60 m/s, 11.74 vs. 13.49 kHz/[m/s]) in myositis patients are significantly lower than those in healthy controls on transverse and longitudinal axes, while SCM (6.94 vs. 7.25 kHz/[m/s], 9.49 vs. 10.51 kHz/[m/s]) only has differences in the dispersion slope (p < 0.05). We further calculated the sum of viscoelasticity of these four groups of muscles. The overall shear wave velocity (10.82 vs. 11.83 m/s, 16.72 vs. 18.6 m/s) and dispersion slope (55.54 vs. 59.49 kHz/[m/s], 80.46 vs. 96.99 kHz/[m/s]) of myositis patients were lower than that of the healthy controls, which was consistent across transverse and longitudinal axes (p < 0.05). Correlation analysis identified significant negative correlation between CK and LDH and muscle viscoelasticity, with correlation coefficients of -0.56 to -0.60 and -0.57 to -0.71, respectively (p < 0.05).

Conclusion: The viscoelasticity of muscle in IIM patients was significantly decreased, which was moderately to strongly correlated with muscle injury markers. Shear wave elastography can quantitatively evaluate muscle injury, it may serve as an imaging marker for the diagnosis and activity evaluation of myositis.

Figure 1. A 60-year-old male with dermatomyositis. B-mode ultrasound showed hyperechoic nodule in the right upper arm muscle, indicative of muscle mass increase. Shear wave elastography of the biceps brachii muscle revealed decreased shear wave velocity and dispersion slope, consistent with muscle injury.
CEREBROVASCULAR AND CAROTID ARTERIAL RISK OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES IS INCREASED AND CAN BE PREDICTED BY ENA POSITIVITY

Keywords: Biomarkers, Cardiovascular disease, Myositis

K. Triantafyllias1,2, S. Gauch2, L. Cavagna3, A. Schwarting2,3, *Rheumatology Center Rheinland-Palatinate, Rheumatology, Bad Kreuznach, Germany; 1Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany; 2University and IRCSS Policlinico S. Matteo Foundation of Pavia, Rheumatology, Pavia, Italy

Background: Patients with idiopathic inflammatory myopathies (IIM) are under increased cardiovascular (CV) and cerebrovascular (CVB) risk [1]. Nevertheless, data on diagnostic tools that could assist CV and CVB patient screening in IIM are scarce. Surrogate markers of CV and CVB risk have been shown to improve risk stratification in the general population and have thus been endorsed by the European Society of Cardiology (ESC) for use in clinical practice. In particular, stiffness of the aortic vasculature and sonography of the carotid arteries are associated with high levels of evidence regarding their CV- and CVB-risk predicting value.

Objectives: Therefore, aim of this study was to examine an oscillometric marker of aortic stiffness and sonographic indices of carotid atherosclerosis and rigidity in a cohort of IIM patients. Moreover, we sought to investigate their relationships with patient- and disease-associated parameters.

Methods: Patients from two large Rheumatology Departments, who have been diagnosed with IIM according to the ACR/EULAR criteria, were recruited. Carotid-femoral pulse wave velocity (cfPWV; gold standard) was used for the examination of aortic stiffness. Moreover, B-mode and Doppler sonography examinations of the common- and internal carotid arteries (CCA, ICA) were performed to assess plaque presence and/or possible abnormalities of carotid intima media thickness (cIMT), as well as vascular resistance and pulsatility indices (RI, PI). The ESC-SCORE (Systematic Coronary Risk Evaluation) was also assessed in all eligible patients.

Results: 73 IIM patients (58.9%; age 58 (50-65, IQR) and 88 healthy subjects (84.1%; age 51 (37.57, IQR)) underwent cfPWV examinations in the context of the study (Table 1). A subgroup of the patients (n=83) was additionally evaluated via carotid sonography. IIM patients showed statistically significantly higher cfPWV-values [7.92 m/s (6.49-9.26, IQR), vs. 6.72 m/s (6.0-7.69, IQR); p<0.001] and cIMT-values [0.92 mm (0.77-1.1, IQR), vs. 0.8 mm (0.66-0.88, IQR); p<0.001], compared to controls. CCA- and ICA- resistance and pulsatility indices were also statistically significantly higher in the patient group (all; p<0.01). Almost all of these differences remained significant after adjusting for confounding factors, such as age, smoking, BMI, hypertensive treatment and cholesterol levels (padj<0.001), CCA-PI and ICA-PI remained significant after adjusting for confounding factors, such as age, smoking, BMI, hypertensive treatment and cholesterol levels (padj<0.001). Interestingly, patients with ENA-positivity showed higher CCA-RI values compared to their counterparts [0.85 (0.765-0.88, IQR) vs. 0.77 (0.72-0.82, IQR), p=0.044].

Conclusion: Hereby, we could show that IIM patients have a higher level of carotid atherosclerosis, as well as increased vascular resistance and pulsatility, compared to healthy subjects. Thus, a higher CBV and CV risk can be postulated.

To our knowledge, this is one of the largest surrogate marker studies in the field of IIM and the first one to show that positivity of myositis associated antibodies (MSA) can be an independent predictor of a higher carotid resistance index. Therefore, MSA-status should be taken into account during CVB risk stratification of IIM.

CEREBROVASCULAR AND CAROTID ARTERIAL RISK OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES IS INCREASED AND CAN BE PREDICTED BY ENA POSITIVITY

ANTIBODY PREDICTIONS OF PROGNOSIS IN IDIOPATHIC INFLAMMATORY MYOPATHY ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Autoantibodies, Myositis, Lungs

J. Hannah1,2, A. Lawrence1, J. Martincovic1, M. Naqvi3, S. S. Ali3,3, C. Stock4, C. Owens5, A. Devaraj6, L. Pollard3, S. Agarwal7, A. Atienza-Mateo8, A. Patel9, A. West10, K. Tinsley11, H. Robbie12, F. Chua13, B. Lams14, A. Wells15, S. Norton16, J. Galloway17, E. Renzoni18, P. Gordon19, 1King’s College Hospitals NHS Trust, Department of Rheumatology, London, United Kingdom; 2King’s College London, Department of Academic Rheumatology, London, United Kingdom; 3Guys and St Thomas’ NHS Trust, Department of Respiratory Medicine, London, United Kingdom; 4Royal Brompton and Harefield Hospitals, Interstitial Lung Disease Unit, London, United Kingdom; 5University Hospital Lewisham, Department of Rheumatology, London, United Kingdom; 6Marques de Valdecilla University Hospital, Division of Rheumatology, Santander, Spain; 7King’s College Hospital, Department of Respiratory Medicine, London, United Kingdom; 8King’s College Hospitals NHS Trust, Department of Radiology, London, United Kingdom

Background: IIM-ILD follows a varied clinical course. Serological profile can help predict clinical phenotype, but impact on ILD prognosis is less clear.

Objectives: This multicentre UK cohort study examines whether serological profile can predict mortality and change in lung function over time.

Methods: Patients with IIM-ILD were identified in 3 NHS trusts from local databases. Adults with ILD meeting IIM diagnostic criteria or Interstitial Pneumonia with Autoimmune Features (IPAF) with at least one MSA validated by Western Blot were included. Baseline characteristics from time of presentation were compared across antibody groups and across survivors/deceased at 2 years. Survival analysis looking at time to death (or lung transplant) for duration of available follow-up was modelled by Cox-Proportional Hazards comparing each antibody individually to all others. Models were adjusted for age, gender, ethnicity, presence of overlap CTD/malignancy, smoking and site. Regression models were also used to observe trends in lung function parameters over time.

Results: Of 430 included patients, 68% were female, 46% were of White ethnicity. 81% met IIM criteria, 19% were IPAF. Mean follow up duration was 4.3 years. Common antibodies were to Ros2, Jo1, PL12, MDA5 (n=195, 126 & 42 respectively). 10% had evidence of pulmonary hypertension within 1 year of diagnosis, 4% had malignancy within 3 years. Baseline characteristics of survivors vs fatal cases at 2 years showed survivors were younger (51.4 vs 61.7 years), more likely to have never smoked (69% vs 44%), less likely to have been hospitalised at diagnosis (15% vs 52%) and had a lower Charlson Comorbidity Index. Survivors had lower CRP, higher CK & higher baseline FEV1/FVC/TLCO. Imbalance in age, BMI, CK and comorbidity compared to healthy subjects. Thus, a higher CBV and CV risk can be postulated. To our knowledge, this is one of the largest surrogate marker studies in the field of IIM and the first one to show that positivity of myositis associated antibodies (MSA) can be an independent predictor of a higher carotid resistance index. Therefore, MSA-status should be taken into account during CVB risk stratification of IIM.

* counts of < 5 suppressed for anonymity
and PL7 had high HR (2.07, 95% CI 1.44-2.99). RNP showed worse prognosis on adjusted analysis (HR 1.88, 95% CI 1.25-2.84) (Table 1). Regression models suggest that compared to other antibodies, %pred FVC in MDA5 improves over the first 3 years, in PL7 it drops, and in Jo1 it is no different (Figure 1). MDA5 % pred FEV1 also showed improvement, but in Ku it was lower than other antibodies from 21 months. There were no significant differences in % pred TLCO between antibodies.

REFERENCES: NIL.

Figure 1.

Conclusion: There is strong evidence that antibody status associates with clinical outcomes, both in terms of progression of lung disease and mortality, suggesting pathogenetic differences. MDA5 predicts a high risk of death early on in disease course, whilst Jo1 associates with lower mortality. PL7 and RNP were associated with a higher mortality in the regression models. MDA5 predicts a high risk of death early on in disease course, whilst Jo1 associates with lower mortality. PL7 and RNP were associated with a higher mortality in the regression models.

Keywords: Myositis, Registries

Background: Idiopathic inflammatory myopathies (IIM) are a group of rare, heterogeneous diseases in which the hallmark feature is chronic inflammation of skeletal muscle leading to muscle weakness. Initial conventional therapy is based on expert opinion and includes glucocorticoids in combination with methotrexate, azathioprine, or mycophenolate. If this therapy is not sufficiently effective, second line therapy (calcineurin inhibitors or IVIG) may be considered. If still insufficient, escalation to rituximab or cyclophosphamide is considered. Agents not included in conventional recommended therapies have also been used and are being studied in the management of IIM.

CONCLUSION: Despite published recommendations to combine glucocorticoids with another immunosuppressive drug as part of first line therapy for IIM, many individuals with IIM are not prescribed concomitant DMARDs. In this cohort, there were no significant differences in IIM subtype, disease duration, or calendar-year by conventional vs nonconventional therapy at study entry. A relatively small number of participants (2%) were on corticosteroid alone (23%) or were on first line therapy but without a corticosteroid (17%). A relatively small number of participants (2%) were on second line therapy, and none were on third line therapy at baseline. About 9% reported use of a nonconventional DMARD, and the remaining 6% reported no treatment. Those who reported no therapy were more likely to be male and had higher global severity scores. Across 504 person-years of observation, 47% reported first line treatment, 10% reported second line, and 3% reported third line as the most advanced conventional therapy received. The remaining participants reported either no conventional or no treatment.

Conclusion: Despite published recommendations to combine glucocorticoids with another immunosuppressive drug as part of first line therapy for IIM, many individuals with IIM are not prescribed concomitant DMARDs. In this cohort, there were no significant differences in IIM subtype, disease duration, or calendar-year by conventional vs nonconventional therapy at study entry. A relatively small number of participants with IIM reported receiving no treatment during observation, which may be due to significantly shorter follow up time in that subgroup. Future work should examine treatment response and changes in disease activity with changing lines of treatment.
Figure 1. Treatment progression among individuals in FORWARD with IM. Baseline (at study entry) treatment category is shown on the left, and ultimate treatment category (during observation) is shown on the right. First line = glucocorticoid + methotrexate, azathioprine, or mycophenolate. Second line = calcineurin inhibitors or IVIG. Third line = rituximab or cyclophosphamide.

POS1237 MICROVASCULAR DAMAGE IN AUTOIMMUNE CONNECTIVE TISSUE DISEASES: A CAPILLAROSCOPIC ANALYSIS FROM 20 YEARS OF EXPERIENCE IN A EULAR TRAINING AND RESEARCH REFERRAL CENTER FOR IMAGING

Keywords: Diagnostic Tests, Myositis, Systemic sclerosis

E. Hysa, S. Sammori1, C. Pizzorni1, E. Gotelli1, A. Cere1, C. Schenone1, G. Ferrari1, R. Campitelli1, V. Gerli1, S. Paolino1, A. Sulli1, V. Smith1, M. Cutolo1.

Background: Nailfold videocapillaroscopy (NVC) safely allows the detection of microvascular damage which can vary in terms of extent and severity (validated NVC patterns) in patients with Raynaud's phenomenon (RP) secondary to autoimmune connective tissue diseases (CTDs).

Objectives: The prevalence of the morphological capillary findings was retrospectively evaluated in a wide cohort of patients with RP secondary to a CTD at the time of the first single NVC analysis, independently from their current treatment, autoantibody profile and comorbidities.

Methods: One-thousand-one-hundred-eighty-one (1181) patients affected by CTDs (1065 females, mean age 54.1 ± 16.2, mean disease duration 4.5 years ± 3) were analysed from 2001 to 2021. The considered CTDs, diagnosed through the classification criteria available at the time of the enrollment, included: systemic sclerosis (SSc, 51%), undifferentiated connective tissue disease (UCTD, 26%), mixed connective tissue disease (MCTD, 6%), dermatomyositis (DM, 3%), systemic lupus erythematosus (SLE, 9%), Sjögren's syndrome (SS, 3%) and primary anti-phospholipid syndrome (aPS, 2%). The capillaroscopic parameters were classified according to the CAP Fast Track Algorithm and distinguished between scleroderma-pattern (specific NVC alterations) and non-scleroderma patterns (non-specific NVC alterations) [1]. The presence of specific NVC findings detectable with a progressive microangiopathy in SSc patients (“early”, “active”, “late” patterns) have been searched also in other CTDs, beyond SSc. The “scleroderma-like pattern” was defined when a concomitant mix of the specific abnormalities of the SSc-patterns (namely: giant capillaries, loss of capillaries, capillary dilations, microhaemorrhages, abnormal shapes) was detected without fitting the single definition of “Early”, “Active” or “Late” pattern [2].

Results: Among CTDs, the mean capillary density (1 linear mm) was significantly lower among all the CTDs (respectively, in 73%, 99% and 70% of SSc patients and in 73%, 96% and 70% of DM patients, Figure 1). The non-specific abnormalities of capillary morphology, such as the ramifications (abnormal shapes as expression of neoangiogenesis) were significantly more frequent in SSc, MCTD and APS among all the CTDs (respectively, in 48%, 41% and 36% of cases). Moreover, giant capillaries and abnormal shapes were detected in 61% and 41% of MCTD patients. In APS, the most significant prevalence of microhaemorrhages (50%) was observed compared with other CTDs, to the exclusion of SSc and DM being detectable in 70% of cases. No significant damages were observed in SS and SLE patients (Figure 1).

Conclusion: This large sample size of CTDs patients, collected over 20 years of analysis, confirms the highest specificity and severity of the NVC microvascular damage respectively in SSc and DM patients, when compared to other CTDs. Those data will be used to implement easy algorithms to distinguish scleroderma patterns, from non-scleroderma and scleroderma-like patterns.

POS1238 FIRST EFFICACY FOR CAR-T CELL TREATMENT IN REFRACTORY ANTISYNTHETASE SYNDROME

Keywords: Treat to target, Myositis, Remission

J. Taubmann1,2, F. Müller2,3, S. Boeltz1,2, J. Knitza1,2, S. Völkl2,3, M. Aigner2,3, A. Kleyer2,3, I. Minnopoulou2, F. Locatelli2, M. A. D’agostino2, R. Gary2, S. Krestchmann2,3, S. Krhardt1,2, D. Mougiakakos2,3,4, G. Krönke1,2, M. Andrea2,3, G. Schett1,2, Department of Internal Medicine 3, Rheumatology and Immunology, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; 3Department of Internal Medicine S-Hematology and Oncology, Universitätsklinikum Erlangen and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany; 4Ospedale Pediatrico Bambino Gesù, Bambino Gesù, Department of Pediatric Onco-Hematology and Transfusion Medicine, Roma, Italy; 5Catholic University of the Sacred Heart, Division of Rheumatology, Roma, Italy; 6Hämatologie und Onkologie, Universitätsklinikum Magdeburg A.d.R. Universitätsklinik für Hämatologie und Onkologie, Magdeburg, Germany

Background: We previously reported that deep B cell depletion using a single infusion with autologous CD19 chimeric antigen receptor (CAR) T cells induced drug-free clinical remission in patients with severe systemic lupus erythematosus [1,2]. Whether other forms of severe autoimmune disease are sensitive to treatment with CD19 CAR-T cells has been unknown to date. Antisynthetase syndrome (ASS) is a autoimmune disease that affects muscles, joints, skin and lung. ASS can be very severe and life-threatening needing effective and fast treatment. This abstract presents the first evidence that severe ASS is highly sensitive to treatment with autologous CD19 CAR-T cells.

Objectives: To test whether administration of CD19 CAR-T cells is tolerable and effective in patients with severe refractory Antisynthetase syndrome.

Methods: Autologous CD19 CAR-T cells were prepared from leukapheresis specimen after enrichment of T cells and transfection with MB-CART19.1

Figure 1. Microvascular changes detected with nailfold videocapillaroscopy in severe refractory antisynthetase syndrome (aPS)
Results: Two anti-Jo1 AS patients (patient 1: 41-year-old male, patients 2: 43-year-old female) were treated with CD19 CAR-T cells. Both patients presented with active myositis with CK levels of 3055U/l, respectively. Patient 1 showed involvement of the muscles, skin and lungs; patient 2 showed involvement of muscles, skin, joints and lungs. Patient 1 did not respond to 5 different immunosuppressive treatments including cyclophosphamide and rituximab, while patient 2 did not respond to 10 treatments including cyclophosphamide, rituximab and ocrelizumab. CAR-T cell treatment was well-tolerated. Only mild CRS (grade I) was observed in both patients. Patient 2 had signs of mild self-limited ICANS (grade I discrete ataxia for a few days) two weeks after CAR-T treatment. In patient 1, CAR-T cells expanded to a maximum of 60 cells/µl on day 8, in patient 2 to 1524 cells/µl on day 8. Expansion of CAR-T cells paralleled with the complete depletion of circulating B cells. B cell aplasia lasted for 119 days in patient 1, while patient 2 is still in B cell aplasia (day 60). Both patients experienced normalization or significant reduction in CK levels (patient 1: CK<120 days: 70 U/l, patient 2: CK<60 days: 311 U/l), major clinical improvement according to 2016 TIS and could stop all immunosuppressive treatment (5 U/l; cut-off 25U/l, Orgentec ELISA, Mainz, Germany) in patient 1, while patient 2 awaits follow up measurement.

Conclusion: Taken together, these data suggest that CD19 CAR T-cell therapy provides a possibility to interrupt with severe ASs leading to drug-free remission, resolution of muscle and lung inflammation and abrogation of disease-associated autoimmunity.

lentiviral vector (Milenyi) encoding for a 4-1BB based CAR targeting CD19. Cells were expanded for 12 days and 1 million CAR-T cells/kg body weight were administered as a single intravenous infusion after standard conditioning therapy with cyclophosphamide/fludarabine, as described previously [1,2]. All disease-related treatments were stopped before CAR-T cell administration. Patients were followed up in outpatient care for the first 10 days after CAR-T cell administration, thereafter weekly until the end of the first month, then monthly for three months and every three months later. Tolerability was assessed by monitoring for Cytokine-Release Syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS). Efficacy was assessed by CK levels, good response according 2016 ACR/EULAR total improvement score (TIS), imaging of muscles and lungs and successful cessation of all immunosuppressive treatments including glucocorticoids.

Methods: ILD patients[5]. In clinical practice, there is still an urgent demand for sensitive and specific biomarkers of novel CAR-T cell therapy. Janus kinase inhibitor, which targets the IFN pathway, can be a valuable biomarker for monitoring disease activity and predicting mortality in anti-MDA5+DM patients.

Background: Intersitial Lung Disease (ILD) is the most common cause of mortality in myositis and there is lack of randomized clinical trials for myositis-associated ILD (MA-ILD). A T-cell mediated pathogenesis has been postulated for MA-ILD, and abatacept (ABA) is a T cell co-stimulatory modulator.

Objectives: Our primary objective was to evaluate the efficacy, safety and tolerability of ABA (125 mg SQ weekly) combined with standard of care (SOC) vs. placebo/SOC in MA-ILD patients in a multi-center, double-blind, randomized placebo-controlled proof of concept clinical trial.

Methods: 20 patients (pts) with anti-synthetase antibody (Anti-Syn Ab) were enrolled across 5 centers for 24 weeks in a randomized placebo-controlled phase (RCT) followed by an open label extension (OLE) for 24 weeks. Active myositis was not required but pts must have had active ILD (new onset or worsening requiring treatment) and previously failed ≥1 SOC drug for ILD. Pts were required to be on stable SOC (glucocorticoids (GC)/1 immunosuppressive (IS) agent (azathioprine or mycophenolate) prior to the trial as well as stable SOC IS throughout the trial. A recommended GC taper was instituted. The primary end-point was the change in Forced Vital Capacity (FVC) (in ml) change from baseline to week 24. Secondary endpoints included FVC changes over 48 weeks, patient reported outcomes (PRO) of dyspnea (UCSD-shortness of breath questionnaire; range 0-120, MIDC of 8) and DLCO corrected % predicted (DLCO) at 24 and 48 weeks. Mixed effect modeling was used for analysis and the study was not powered for primary or secondary outcomes.

Results: A total of 20 anti-Syn Ab positive pts (mean age of 57, 45% female and 85% Caucasian, Jo-1, 55% were randomized to ABA (n=9) and placebo (n=11). All but 1 pts completed 48 weeks of the trial. There was no significant or clinically relevant difference in median FVC (ml) from baseline to week 24 between ABA (-40ml) and placebo (30ml), p = 0.97. However, the median FVC (ml) change from baseline to week 48 was 140ml and -40ml, in ABA vs. placebo (p=0.15), with a 180ml difference in favor of the ABA group. FVC% predicted remained stable (±5%) or improved (>5%) without death or drug rescue in 75% (68/8) and 56% (24/43) of pts at week 24 and week 48, in ABA vs. placebo, respectively. The median DLCO change from baseline was -4.5% and -10.5% at week 24, 6.5% and -2.7 at week 48, in ABA vs. placebo group, respectively. DLCO remained stable (±5%) or improved (>5%) without death or drug rescue in 75% (47/63) and 56% (24/43) of pts at 24 and 48 weeks, in ABA vs. placebo, respectively. Dyspnea improved by an MCID of 8 without requiring drug rescue or death in 22% (2/9) and 45.5% (5/11) of pts at week 24, 53% (5/9) and 40% (4/10) at week 48, in ABA vs. placebo, respectively. Dyspnea improved by median of 1 and 3 at week 24, 13 and 5 at week 48 in ABA vs. placebo, respectively. Dyspnea improved by an MCID of 8 without requiring drug rescue or death in 22% (2/9) and 45.5% (5/11) of pts at week 24, 50% (4/8) and 18% (2/11) at 48 weeks in ABA vs. placebo, respectively. There were 3 severe adverse events (1 in RCT, 2 in OLE) in 2 pts requiring hospitalization in the ABA group for progressive respiratory failure and 1 died (at 24 weeks). There were 36 and 23 adverse events among 9 placebo and 10 treatment groups of pts ABA was well tolerated.

Conclusion: MA-ILD ABA-treated subjects showed similar FVC, DLCO and dyspnea PRO trends compared to placebo at 24 weeks but clinically and numerically meaningful trends were observed in ABA-treated subjects at week 48.

These results suggest the need for a larger randomized study of ABA in MA-ILD. Abatacept was relatively safe and well tolerated in the cohort.

**Scleroderma, myositis and related syndromes**

**Keywords:** Inflammatory arthritis, Imaging, Myositis

P. Welker, D. Franke, A. Briel, V. Failli, Chantel - University Medicine Berlin, Functional Anatomy, Berlin, Germany; n nanopET GmbH, Imaging, Berlin, Germany

**Background:** Myopathies with main symptoms of muscle pain and weakness can have a wide variety of triggers, be characterized by different courses and localizations, and occur as side effect of rheumatic diseases. They have also recently come into focus as sequelae after systemic viral infections, for example as post-acute Covid-19 syndrome. Inflammatory reactions (Polyomysitis, PM) are often difficult to differentiate from non-inflammatory myalgias. Clinical examinations and analysis of serum parameters are helpful, but do not always lead to clear results due to overlapping syndromes. In addition to pathogenic-related myositis (Lyme disease), LD, muscle inflammation can also occur in autoimmune-caused rheumatic diseases such as systemic sclerosis (SSc), rheumatoid arthritis (RA), or polymyalgia rheumatica (PMR). Furthermore, overexertion, degeneration, or psychosomatic influences (fibromyalgia, FM) can lead to the symptom of muscle pain.

**Objectives:** The present work investigates the potential of NfRI-F0I feature assessment in diagnosing patients with muscle weakness and muscle pain to better explore therapy options.

**Methods:** NfRI-FOI analyses of patients (n = 200) without clinical symptoms (Ref. n = 31), or the diagnosis of osteoarthritis (OA) (n = 35) were compared with PM patients (n = 9), and patients diagnosed with autoimmune RA (n = 35), SSc (n = 34), Sjogren Syndrome (SS, n = 20), or PMR (n = 5). In addition, patients with diagnoses of LD or primary FM (n = 31) were examined. Indocyanine green as fluorescence dye was injected and the FOI images of both hands were evaluated from 0-240s (Prista Video Image, PVI), or in the late period P3 (150-240s). Signal intensities (SI) were created from the summation images. For characterization of the cohorts, serum parameters were determined.

**Results:** Since the detection of serum JO-1 antibodies can be considered as reliable evidence of myositis, patients with this verification examined first. In addition to increase of SI in PVI (p<0.0001), 8/9 PM patients show stronger accumulation in P3 in the anatomical position of hand muscles, and in the tendon-muscle junction of the forearm compared to the Ref group (Figure 1). In the cohort of patients with PMR, the PVI SI was also increased (p<0.0001). Stronger P3 accumulation was observed in 3/5 patients. However, besides accumulation in the joints as the main site of inflammation in this disease, signal increase was detected mostly in the muscle-tendon transition, which could be also attributed to degenerative changes due to the high age of this cohort. That is also true for the patients in the OA cohort, but with lower SI both in PVI and P3. In addition, increased PVI SI was detected in all other disease cohorts (p<0.01). However, increased accumulation in P3 can only be detected in some of the patients of these cohorts and predominantly in the muscle-tendon transition. Most frequently, patients with increased accumulation in P3 were identified in the groups of RA and SS. However, increased accumulation in P3 was also detected in 48% of patients diagnosed with fibromyalgia, but only in the muscle-tendon junction.

**Conclusion:** The study demonstrates that changes in the microcirculation in inflammatory processes in the context of myositis correlate with a late phase dye accumulation during a NfRI-FOI examination. This could provide valuable information for differential diagnoses of inflammatory versus non-inflammatory myopathies to optimize therapy. NfRI-FOI could also potentially be used for the screening of myositis in virus-related diseases (e.g., Covid-19).

**Figure 1:** Examples of NfRI-FOI images in patients: A. without clinical symptoms (Ref), B. PVI positive Polyomysitis (PM), C. Polyomysitis rheumatica (PMR), D. Rheumatoid arthritis (RA). Analysis of fluorescence dye distribution 0-240s (summations image, PVI), or in late phase 150-240s (P3). The figure demonstrates significant dye accumulations in inflammatory tissues with a focus in the areas of the muscles and tendons in PM, and in the joints in PMR and RA.

Background: Early pulmonary arterial hypertension (PAH) diagnosis and treatment are crucial to improve systemic sclerosis (SSc) patients' outcomes. In PAH the progressive pulmonary vascular remodeling leads to an increasing load on the contracting RV and an altered right ventricular - pulmonary arterial (RV-PA) coupling. The RV-PA coupling describes the RV adaptation to its afterload [1]. Tricuspid annular plane systolic excursion/systolic pulmonary artery pressure (TAPSE/sPAP) ratio is the validated non-invasive estimation of RV-PA coupling [2]. In the new 2022 pulmonary hypertension (PH) guidelines, TAPSE/sPAP ratio has been included among the additional echocardiographic signs suggestive of PH and the echocardiographic parameters for 1-year mortality risk assessment [3]. However, to date, the role of TAPSE/sPAP ratio in SSc is underinvestigated [4-6].

Objectives: The primary aim of the study was to assess the predictive role of TAPSE/sPAP ratio for PH diagnosis in the SSc European Scleroderma Trials and Research (EUSTAR) cohort. The secondary aim of the study was to evaluate the prognostic role of TAPSE/sPAP ratio in predicting mortality in the SSc EUSTAR cohort.

Methods: Eligible patients were systemic sclerosis (SSc) patients registered in the EUSTAR database with at least one visit recording TAPSE and sPAP data. Individual centres were required to provide TAPSE and sPAP data at 12±3 months before right heart catheterization (RHC). Logistic regression analysis was applied to analyse the predictive ability of TAPSE/sPAP ratio for PH diagnosis. Cox regression analysis was performed to evaluate TAPSE/sPAP ratio as a predictive factor for all-cause mortality.

Results: 2555 SSc patients met the inclusion criteria for this study with 355 SSc patients having available RHC data at baseline. PH was confirmed by RHC in 195 SSc patients (54.9%). TAPSE/sPAP ratio ≤0.55 mm/mmHg [OR 0.251 (95% CI 0.084-0.753), p<0.05] and FVC/DLCO [OR 2.568 (95% CI 1.227-5.375), p<0.05] were significantly associated with PH diagnosis. In logistic regression analysis with echocardiographic parameters at 12±3 months before RHC, TAPSE/sPAP ratio <0.55 mm/mmHg [OR 0.251 (95% CI 0.084-0.753), p<0.05] and FVC/DLCO [OR 2.568 (95% CI 1.227-5.375), p<0.05] were significantly associated with PH diagnosis. In multivariate Cox regression analysis, TAPSE/sPAP ratio ≤0.32 mm/mmHg [HR 0.310 (0.164-0.585), p<0.001] was the most significant predictive factor for all-cause mortality.

Conclusion: TAPSE/sPAP ratio ≤0.55 mm/mmHg is a predictive risk factor for PH. TAPSE/sPAP ratio ≤0.32 mm/mmHg is a predictive risk marker for all-cause mortality.

RESULTS OF A PHASE 2A STUDY OF CILNIDIPINE, A NOVEL DAILY ORAL CALCIUM CHANNEL BLOCKER WITH N-CHANNEL SELECTIVITY, FOR THE TREATMENT OF RAYNAUD’S AND OTHER SYMPTOMS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Clinical trials, Disease-modifying drugs (DMARDs)

A. Sterlnich1, M. Shanahan2, E. Morton3, E. Briggs4, I. Hunt5, Z. Reed6, A. Weragoda7, L. Weerakoon3, M. Todd4, J. Ituls Medical Center, Anesthesiology and Pain Medicine, Boston, United States of America; Aisa Pharma, Inc, Clinical Development, Boston, United States of America; Flinders Medical Center, Rheumatology, Adelaide, Australia; Aisa Pharma Australia Pty Ltd, Clinical Operations, East Lindfield, NSW, Australia

Background: Systemic Sclerosis (SSc) is a rare autoimmune disease with fibrosis, changes in the skin, vasculature, joints and internal organs. Diffuse disease involves lung, heart and kidney and 10-year mortality is ~35% [1]. Raynaud’s attacks occur in ~95% of SSc patients. Severe Raynaud’s (RP) affects patients’ health status more than depression, obesity, and heart disease [2]. No treatment for Raynaud’s is approved, but calcium channel blockers (CCBs) are first-line treatment. Cilnidipine, a 4th generation CCB approved for hypertension in Asia, has been shown to be safer than other CCBs in treating hypertension, and has beneficial effects on the kidney and heart. Cilnidipine is more selective for N-type Ca channels, and improves analgesia, autonomic and endothelial function [3]. Cilnidipine might be repurposed for SSc-RP patients.

Objectives: We studied safety and preliminary efficacy of cilnidipine use in SSc-RP, dose response and co-administration of a low dose PDE-V inhibitor. Results are compared to a 2021 meta-analysis of CCB use in SSc-RP.

Methods: RECONNOITER-1 is a two-part, planned 78 patient trial. In Part 1, we evaluated safety, dose, efficacy and co-administration of tadalafil. Dose groups were cilnidipine 10mg and 20mg, alone and with tadalafil 5mg, tadalafil alone and placebo. The 1st endpoint was reduction in weekly frequency of RP. 2nd endpoints included Raynaud’s Score Condition Score (RCS), pain, severity, duration, and a validated PRO (SHAQ). The DSMB reviewed data on the first 27 patients in 8/2022.

Results: The ITT population was 27 patients, the mITT 24. Results are reported for the mITT population. Cilnidipine-only treated patients (n=7) had a reduction in weekly attacks of 42.2% versus 18.9% in placebo (n=4). Dose response was seen in weekly attack frequency and severity. Response was greater in the higher cilnidipine dose group on attack duration and RCS. Tadalafil increased treatment effect with 10 mg but not with 20 mg. Cilnidipine at either dose was well tolerated and only Grade 1 mild AEs were reported with cilnidipine (1/7), with no treatment discontinuations due to AEs. The DSMB halted Part 1 early based on meeting study goals.

Conclusion: In this preliminary study, cilnidipine was well-tolerated and efficacy trends were seen. A published meta-analysis of CCB use for RP finds AEs >46% and treatment discontinuation in >30% of patients [4]. Cilnidipine appears superior in safety to commonly used CCBs (P=0.0247). Our results replicate the improved safety in hypertension treatment. PRO results (SHAQ) also favor the 20 mg dose of cilnidipine over placebo with a response over placebo, despite the small numbers (n=0.0115). Increased N-type channel blockade may increase safety and efficacy with the drug. Part 2 will compare Cilnidipine 20mg daily to placebo in a crossover trial in 38 patients.

TREATMENT WITH Methylprednisolone IN VERY EARLY SYSTEMIC SCLEROSIS: RESULTS OF THE HIT HARD AND EARLY RANDOMIZED CONTROLLED TRIAL

Keywords: Investor initiated trial, Systemic sclerosis, Randomized control trial

B. Kersten1, J. Lemmers1, A. Vanhaecke1, F. Van den Hoogen1, C. H. M. Van den Ende1, V. Smith2, M. Vonk3, Radboud University Medical Centre, Rheumatology, Nijmegen, Netherlands; Ghent University Hospital, Rheumatology, Gent, Belgium

Background: Accumulating evidence indicates that inflammatory mechanisms drive vasculopathy and fibrosis in Systemic Sclerosis (SSc), mainly in very early disease [1]. Therefore, anti-inflammatory therapies, such as glucocorticoids, might be effective in this early pathophysiological phase. According to the VEDOSS criteria, patients can be classified as very early SSc when a combination of Raynaud’s phenomenon, SSc associated autoantibodies, early SSc nailfold capillary pattern and puffy hands are present [2]. We hypothesize that inhibition of the inflammatory process, treatment with glucocorticoids will induce remission in patients with very early SSc.

Objectives: We performed a double-blind, randomized, placebo controlled, multicenter trial in patients who meet the VEDOSS criteria, to analyze the efficacy of high dose methylprednisolone.

Methods: The trial was initiated between January 2017 and February 2021 at the Department of Rheumatology of the Radboud University Medical Centre in Nijmegen, The Netherlands and the Department of Rheumatology of the University Hospital Gent, Belgium. Patients were randomly assigned (2:1) to methylprednisolone 1000 mg intravenously for 3 consecutive days monthly for 3 months, or placebo. Patients were stratified by sex, age, and center. The primary endpoint was difference in nailfold capillary density, measured by nailfold microscopy at week 13. Changes in capillary density after 52 weeks, change in number of mega capillaries, signs and symptoms of disease progression, time to disease progression and general health utilities were secondary outcomes.

Results: Baseline characteristics were comparable between the 2 groups. Thirty patients were randomly assigned to receive methylprednisolone (n=21) or placebo (n=9). No significant difference in change in nailfold capillary density was found at week 13, mean -0.5 (95% CI 1.1 to -2.0) (Table 1). Moreover, no differences between groups in secondary outcomes were observed, except for a difference in Visual Analogue Scale gastrointestinal complaints assessed by the Gastrointestinal Tract questionnaire in favor of the methylprednisolone group. Thirty-seven percent of patients, 4 in the placebo group and 7 in the methylprednisolone group, had disease progression during the 1 year follow up with no difference between groups (Figure 1). A relevant pulmonary function decline was seen in 23% of patients, 2 in the placebo group and 5 in the methylprednisolone group, respectively. No serious adverse events were reported.

Conclusion: We report data from the first ever investigator initiated randomized, multicenter, double blinded, placebo controlled trial on treatment with methylprednisolone in very early SSc. We were not able to demonstrate a beneficial effect of methylprednisolone. However, we observed that a substantial proportion of patients showed disease progression underlining the importance of early identification and tight monitoring of signs and symptoms of disease progression early in the course of the disease to consequently start potential treatment in this category of patients. This study shows that it is feasible to perform an intervention study with patients with very early disease.

EFFECTS OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD) IN SUBGROUPS BY DISEASE ACTIVITY INDEX

Keywords: Systemic sclerosis, Lungs, Clinical trials

A. Herrick1, J. Pope2, P. Carreira3, C. Miede4, M. Alves5, Y. Allanore6. 1The University of Manchester, Northern Care Alliance NHS Foundation Trust, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2University of Western Ontario, Schulich School of Medicine, Division of Rheumatology, London, Ontario, Canada; 3Hospital Universitario 12 de Octubre, Servicio de Reumatologia, Madrid, Spain; 4mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany; 5Boehringer Ingelheim International GmbH, TA Inflammation Medicine, Ingelheim am Rhein, Germany; 6Descartes University, APHP, Cochin Hospital, Department of Rheumatology, Paris, France

Background: The European Scleroderma Trials and Research group (EUSTAR) disease activity index was developed to assess disease activity in patients with systemic sclerosis (SSc).

Objective: To assess disease activity using a modified version of the EUSTAR disease activity index, and compare outcomes in subgroups by disease activity, in patients with SSC-ILD in the SENSCIS trial of nintedanib versus placebo.

Methods: The SENSCIS trial enrolled patients with SSc with first non-Raynaud symptom in the prior ≥7 years and extent of fibrotic ILD on high-resolution computed tomography (HRCT) ≥10%. Patients were randomised to receive nintedanib or placebo. The EUSTAR disease activity index assesses SSc activity based on modified Rodnan skin score (mRSS), C-reactive protein (CRP) level, diffusing capacity of the lung for carbon monoxide (DLco), presence of digital ulcers, presence of tendon friction rubs, and worsening of skin fibrosis over the previous month (as assessed by the patient). A score ≥2.5 identifies patients with active/very active vs inactive/moderately active disease. For this analysis, a modified version of the index was developed that excluded worsening of skin fibrosis, as data prior to enrolment in the trial were not collected. The modified version had a maximum score of 8.5. We analysed the rate of decline in FVC (mL/year) and adverse events over 52 weeks in patients with low and high SSc disease activity at baseline.

Results: Among 523 patients, 55.1% and 44.9% had modified disease activity index scores of <2.5 and ≥2.5, respectively at baseline. Compared with patients with a score <2.5, those with a score ≥2.5 had a greater extent of fibrosis on HRCT (38.0% vs 34.8%) and lower mean FVC % predicted (69.1 vs 75.1); greater proportions had diffuse cutaneous SSc (70.2% vs 38.9%), were anti-topoisomerase I antibody positive (65.5% vs 58.3%) and were taking mycophenolate (54.0% vs 45.8%). In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in patients with a score ≥2.5 than <2.5 (Figure 1). The effect of nintedanib on reducing the rate of FVC decline was numerically greater in patients with a score ≥2.5 than <2.5, but the interaction p-value did not indicate heterogeneity in the effect of nintedanib between the subgroups (p=0.24). The adverse event profile of nintedanib was similar between the subgroups (Table 1).

Conclusion: Based on a modified version of the EUSTAR disease activity index, almost half of the patients in the SENSCIS trial had active/very active SSc. Nintedanib had a consistent effect on reducing the rate of FVC decline over 52 weeks in patients with low and high SSc disease activity at baseline.

DOI: 10.1136/annrheumdis-2023-eular.2262
Background: The presence of left ventricular (LV) remodeling and dysfunction in systemic sclerosis (SSc) have been well studied to date [1]. Cardiac deformation and impaired right ventricular (RV) free wall contractility patterns in SSc have also been described [2]. High intensity interval training (HIIT) has demonstrated to improve microvascular function in people with SSc [3]. However, the cardiac morphology and function after exercise training in people with SSc have not been studied yet. Echocardiographic indices of RV function [4] were found to be correlated with cardiac-ventricular performance, as assessed by peak oxygen uptake (VO2 peak) in people with SSc.

Objectives: The primary objective of the present study was to assess possible exercise-induced changes in RV morphology and function. A secondary objective was to explore the relationship between VO2 peak and RV echocardiographic indices after exercise training in people with SSc.

Methods: Twenty-eight people with SSc (24 females, mean age 57±21 ± 10.76 yrs.) were randomized into groups A (exercise) and B (control group). Baseline and three-month follow-up assessments included: medical history, anthropometrics, echocardiography, and an arm crank cardiopulmonary exercise testing (CPET). Following the baseline assessments, Group A performed a 3-month supervised exercise program (twice/week) adjunctive to the usual care, while Group B received only the usual care. The supervised exercise training consisted of aerobic and resistance exercises as described previously [5]. The aerobic exercise protocol consisted of HIIT (30s at 100% of peak power output achieved during CPET following by 30s passive recovery) on an arm ergometer.

Results: The average compliance in the exercise program was 90% with no dropouts and no adverse effects. Group A demonstrated a statistically significant increase in VO2 peak by 25.1% (p <0.001), global RV free wall longitudinal systolic strain by 6.69% (p<0.03), RV free wall longitudinal systolic strain of the basal segment by 13.5% (p<0.001) and global RV four-chamber longitudinal systolic strain by 6.76% (p<0.03) after exercise training (Figure 1). No statistically significant difference was observed in group B.

Conclusion: The average compliance in the exercise program was 90% with no dropouts and no adverse effects. Group A demonstrated a statistically significant increase in VO2 peak by 25.1% (p<0.001), global RV free wall longitudinal systolic strain by 6.69% (p<0.03), RV free wall longitudinal systolic strain of the basal segment by 13.5% (p<0.001) and global RV four-chamber longitudinal systolic strain by 6.76% (p<0.03) after exercise training (Figure 1). No statistically significant difference was observed in group B.

32.4-48.6). The main indications for HSCT included MS (68%) and SSc (21%). Successful initial engraftment occurred in the vast majority (98.5%), most times within 30 days from transplant. We observed 70 deaths (5% of 1,389), most (57, 81%) occurring within 2 years. Deaths were most often caused by AD relapse/progression (27%) or infection (24%). At 2 years post-transplant, overall survival was 95.5% (95% CI 94.2-96.5%), PFS was 82% (95% CI 79.6-84.2%), and relapse of AD occurred in 14.8% (95% CI 12.7-17.0%). Non-relapse mortality was 3.2% (2.3 - 4.3) at 2 years. Similar overall survival, PFS, and relapse rates were found for females versus males (biological sex at birth) at both 2 and 5 years post-HSCT (Table 1). Multiivariate analysis was not done due to the heterogeneity of the population and the limited number of events.

Conclusion: Autologous HSCT for autoimmune disease results in high survival and moderately low relapse. Limitations include inadequate precision to stratify by autoimmune disease and transplant regimens.

LUNG ULTRASOUND CHANGES COMPARED WITH AUTOMATED QUANTITATIVE COMPUTED TOMOGRAPHY FOR DETECTING SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Ultrasound, Systemic sclerosis, Lungs

D. M. Reza Beigi1, G. Pellegrino1, N. Landini2, M. Mattone2, G. Paone2, S. Truglia1, F. R. Di Ciommo1, I. Bisconti1, M. Cadar1, K. Stefanonan1, V. Panbianco2, F. Conti1, V. Ricci1, Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy; Sapienza University of Rome, Department of Radiological, Oncological and Anatomo-Pathological Sciences, Rome, Italy; Sapienza University of Rome, Department of Cardiovascular and Respiratory Sciences, Rome, Italy

Background: B-lines and pleural line (PL) changes represent lung ultrasound (LUS) findings for detection of systemic sclerosis-associated interstitial lung disease (SSc-ILD). The ≥10 B-lines cut-off was found to be closely related to moderate ILD on high-resolution chest tomography (CT). Recently proposed Fairchild’s criteria for PL evaluation resulted in high accuracy and reproducibility and a low spending time. Semi-quantitative PL irregularity score by Pinal-Fernandez proved to be superior to total B-lines number to detect SSc-ILD. Although several evidence-based LUS scores have been presented, there is currently a lack of studies involving a comprehensive LUS assessment and comparing different LUS scores with CT, particularly with automated quantitative CT (qCT) assessment.

Objectives: To evaluate the accuracy of quantitative and qualitative LUS B-lines and PL changes for SSc-ILD detection compared to CT with qCT assessment.

Methods: Consecutive SSc patients according to 2013 ACR/EULAR classification criteria underwent LUS by two certified blinded operators using a 14-scans method. The ≥10 B-lines cut-off and Fairchild’s criteria fulfilment were selected as qualitative findings. From quantitative point of view, total B-lines number and the sum of the PL score adapted from Pinal-Fernandez were collected. CT scans performed over a 6 months period were recorded and evaluated by two thoracic radiologists, with further processing by automated texture analysis software.

Results: The study population consisted of 29 SSc patients (Table 1). Agreement between the two operators was almost perfect for Fairchild’s criteria (Cohen’s kappa (k) 0.84) and substantial for ≥10 B-lines cut-off (k 0.78). Both qualitative LUS scores were predictive of ILD presence on CT, with Fairchild’s criteria resulting in slightly more accuracy (Figure 1A). Results were confirmed on multivariate analysis, introducing confounders like age, disease duration, ongoing immunosuppressant therapy, and current/ever smoking (Fairchild’s criteria: p 0.0003 and B-line cut-off: p 0.03). All qualitative and quantitative LUS findings were found to be significantly associated with ILD extension on qCT (p<0.05). Total B-lines number correlated with extension of reticulations and PL quantitative score correlated with extension of both ground-glass and reticulations (Figures 1B and C). Lung bases PL quantitative score, but not B-lines number of the same site, was found to correlate with basal ILD extension on qCT (Figure 1D).

Conclusion: This study highlights the reliability and good accuracy of a comprehensive and systematic LUS assessment for SSc-ILD detection, compared to automated qCT. LUS is increasingly emerging as an accurate, feasible, low-cost and radiation-free pre-CT screening tool. For these reasons, standardisation of LUS appears to be required, in order to achieve its wider use in clinical practice.

PROGRESSION OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS DOES NOT PREDICT FURTHER PROGRESSION

Keywords: Prognostic factors, Lungs, Systemic sclerosis

A. M. Hoffmann-Vold1, L. Petelytska2, H. Fretheim1, I. Barua1, M. O. Becker2, H. J. Bjorkaker1, C. Brunborg1, C. Brun1, P. P. Diep5, R. Dobrota5, M. Duheim5, M. Elhai5, S. Jordan5, E. Langballe1, Ø. Midveldt1, C. Milha5, O. Molberg5, O. Background: Intestinal lung disease (ILD) is a major cause of morbidity and mortality in systemic sclerosis (SSc). In clinical practice, physicians often wait for progression to initiate or escalate therapy. Similarly, progressive SSc-ILD patients

Acknowledgements: NIL.
Disclosure of Interests: None Declared.
DOI: 10.1136/annrheumdis-2023-eular.2835
are recruited into trials to enrich for further progression. These strategies assume that patients with recent ILD progression have a higher risk for further progression. However, this has not been analyzed in SSc-ILD and there is currently no evidence to support such treatment and recruitment strategies.

Objectives: We assessed whether ILD progression predicts subsequent progression using four definitions of progressive disease in two well-characterized SSc-ILD cohorts.

Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT and at least three consecutive annual FVC measurements. For the primary analysis, ILD progression was defined as absolute FVC decline >5% over 12 months. Patients were grouped into progressors (FVC >5% decline) and non-progressors (all others). At the next annual follow up visit, all patients were again assessed for ILD progression. In secondary analyses, we applied other definitions of progression such as:

1. **2022 ATS/ERS/JRS/ALAT guideline criteria with (1) worsening of respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) disease progression on HRCT over 12 months**
2. **INBUILD criteria with (1) FVC decline >10%, (2) FVC decline >20% and (3) worsening of respiratory symptoms or an increased extent of fibrosis on HRCT, or (3) worsening of respiratory symptoms and an increased extent of fibrosis within any timeframe of 24 months.**
3. **Composite criteria with absolute decline in FVC >10%; or FVC >5%-9% and DLCO >15%.**

Multivariable logistic regression was applied, adjusting for known risk factors of ILD progression, including treatment.

Results: Here, 231 SSc-ILD patients from Oslo and Zurich were included, with mean age at onset of 48 years, 55 (24%) being males, 94 (41%) with diffuse cutaneous SSc, 82 (35%) with anti-topoisomerase I antibodies (ATA). Mean FVC was 89%, mean DLCO 64%, 59 (19%) had NYHA functional class ≥3, 35 (27%) extent of ILD >20% and 40% extent >10%. At 12 months, 71 (30.7%) showed FVC decline >5% and were classified as progressors. In multivariable logistic regression, adjusted for age, male sex, ATA, mRSS and immunosuppressive treatment, ILD progression was significantly protective for further progression at the next annual follow-up (Odds ratio 0.28, 95% CI: 0.12-0.63, p<0.002, Figure 1a). When other definitions of progression were applied, similar results were obtained: 44 (19%) fulfilled the guideline criteria, 89 (39%) the INBUILD criteria and 33 (14%) the composite criteria. Multivariable regression analysis adjusted for age, sex and treatment (guideline), for age and sex (composite) and for age, sex, ATA, mRSS, baseline FVC and treatment (INBUILD) showed the same direction as the primary analysis (Figure 1b-d).

Conclusion: ILD progression does not predict further progression using any ILD progression definition in SSc. These results suggest changing current treatment practices, since waiting for progression to initiate or escalate treatment does not seem to be the adequate strategy to identify patients at risk of further progression. It also has important implications for clinical trial design, since selection of progressive SSc-ILD patients does not seem to enrich for a progressive SSc-ILD study population.

J. Catalfi, S. Liem, N. Van Leeuwen, C. Aillaart, T. Huizinga, J. de Vries-Brouwer, 1IIRCIS Istituto Ortopedico Rizzoli, Medicine & Rheumatology Unit, Bologna, Italy; 2Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

**Background:** In systemic sclerosis (SSc), tailoring treatment to each patient’s needs is challenging and it is unclear whether and how patients need to be treated in the long-term. The feasibility of tapering and even withdrawing immunosuppressive therapies in patients with stable disease is still an open question. In the recent past, tapering between males and females or between patients with anticientromere and anti-topoisomerase I antibodies. Overall, immunosuppressive medications were tapered 137 times during the 2968 visits. Of the 107 patients who tapered medications at least once during the follow-up, in 64% of cases it happened during the first three years. In 24 patients, tapering occurred at the last available visit, whereas in 83 patients the management of medications could be evaluated after tapering (246 follow-up visits). In 31 cases, therapies were not changed further. In the other 52 patients, treatment regimen was modified again and in 31 cases we had to either increase the dosage of the current therapy or to initiate a new immunosuppressive drug. Analysing the type of immunosuppressive medication used (Figure 1), we observed that treatment with methotrexate tended to decrease, while mycophenolate mofetil gained favour over the years, especially in men and in patients with mixed or anti-centromere antibodies.

**Conclusion:** In conclusion, tapering of immunosuppressors could be considered in 15% of cases (107 of 708) in our large prospective cohort, and this was successful in approximately two-thirds of cases in which follow-up was available (52 out of 83). If on the one hand early therapeutic intervention might be beneficial and a window of opportunity exists in SSc, on the other hand tapering immunosuppressive treatments might become feasible in a proportion of patients with stable disease.
Patients with SSc-ILD. High-Resolution Computed Tomography (HRCT) parameters, including ground glass opacities, reticular pattern, honeycombing, and pulmonary vascular volume (PVV), quantified and normalized to total lung volume (LV) and expressed as a percentage. The extent of ILD (ILD-extent), given by the sum of ground glass, reticular pattern and honeycombing and the fibrosis score given by the sum of the reticular pattern and honeycombing were also evaluated. The best thresholds for CALIPER measurements were calculated using ROC analysis. Factors associated with death were evaluated by Kaplan-Meier survival curves.

Results: Of the 71 SSc patients included the mean age was of 54.2 ± 11.6 years, (mean disease duration of 10 years) and 90.1% were females. Eleven patients (15.4%) died during follow-up and all had ILD. Most of the CALIPER parameters remained stable over time (Table 1). All CALIPER parameters (except honeycombing), had a significant correlation with forced vital capacity (FVC) at baseline and follow-up (p<0.001). As shown by Kaplan-Meier survival curves, survival was worse among patients with ILD-extent% ≥ 6.32, fibrosis score% ≥ 1.42 and reticular pattern% ≥ 1.41 at baseline, and an ILD-extent% ≥ 4.75, a fibrosis score% ≥ 0.77, a reticular pattern% ≥ 4.34 and a PVV/LV% ≥ 2.8 at 24 months follow-up (Figure 1).

CALIPER PARAMETERS AS PREDICTORS OF MORTALITY IN SYSTEMIC SCLEROSIS: A LONGITUDINAL STUDY

Keywords: Lungs, Systemic sclerosis, Artificial intelligence

F. Godinho De Amorim1, C. Verrastro2, E. Santos2, C. Kayser3. 1UNIFESP, Rheumatology Division, São Paulo, Brazil; 2UNIFESP, Department of Radiology, São Paulo, Brazil; 3UNIFESP, Rheumatology Division, São Paulo, Brazil

Background: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). High-Resolution Computed Tomography (HRCT) and pulmonary function tests (PFTs) are useful for the diagnosis and follow-up of ILD, but have limitations for assessing disease severity and progression, including poor reproducibility of the extent analysis by HRCT and low sensitivity of PFTs. Quantitative CT (QCT) methods, including Computed Aided Lung Informatics for Pathology Evaluation and Rating (CALIPER), are new tools that objectively measures parenchymal abnormalities and vascular features on CT images in a fully automated analysis. [1] This may bring benefits in detecting early disease and in the assessment of prognosis of patients with SSc-ILD.

Objectives: We investigated whether changes in parenchymal abnormalities measured by CALIPER are associated with mortality and their correlation with PFTs.

Methods: Seventy-one patients diagnosed with SSc (ACR/EULAR 2013 criteria) consecutively evaluated from January 2011 to October 2022 at the Scleroderma out-patients clinic at Federal University of São Paulo were retrospectively selected. To be included, patients should have volumetric HRCTs and PFTs performed at baseline and at 24 months of follow-up. All causes of death and clinical variables were collected from clinical records. HRCTs were analyzed using CALIPER. The following parameters were evaluated: ground glass opacities, reticular pattern, honeycombing, and pulmonary vascular volume (PVV), quantified and normalized to total lung volume (LV) and expressed as a percentage. The extent of ILD (ILD-extent), given by the sum of ground glass, reticular pattern and honeycombing and the fibrosis score given by the sum of the reticular pattern and honeycombing were also evaluated. The best thresholds for CALIPER measurements were calculated using ROC analysis. Factors associated with death were evaluated by Kaplan-Meier survival curves.

Results: Of the 71 SSc patients included the mean age was of 54.2 ± 11.6 years, (mean disease duration of 10 years) and 90.1% were females. Eleven patients (15.4%) died during follow-up and all had ILD. Most of the CALIPER parameters remained stable over time (Table 1). All CALIPER parameters (except honeycombing), had a significant correlation with forced vital capacity (FVC) at baseline and follow-up (p<0.001). As shown by Kaplan-Meier survival curves, survival was worse among patients with ILD-extent% ≥ 6.32, fibrosis score% ≥ 1.42 and reticular pattern% ≥ 1.41 at baseline, and an ILD-extent% ≥ 4.75, a fibrosis score% ≥ 0.77, a reticular pattern% ≥ 4.34 and a PVV/LV% ≥ 2.8 at 24 months follow-up (Figure 1).

POS1253

TIMP-1 AS WELL AS IL6 IN PULMONARY CAPILLARIES REFLECT THE COMPLICATIONS AND SEVERITY OF PH IN SYSTEMIC SCLEORDERMAs

Keywords: Cytokines and chemokines, Biomarkers

S. Nakashima1, T. Kameda1, H. Shimada1, R. Wakiya1, T. Miyagi1, Y. Ushio1, R. Mino1, K. Chugo1, H. Dobashi1. Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan

Background: Abnormal production of various cytokines is involved in the pathogenesis of CTD, and the cytokine abnormalities vary according to the type of organ lesion. Recent reports indicate that various cytokine production abnormalities also involve in the pathogenesis of IPAH.1 The differences between PH associated with CTD and other PH-associated cytokines, including IPAH, are not well defined. The relationship between the severity of each PH and cytokines is also not clear.

Objectives: The purpose of this study was to determine the relationship between the cytokine profile in pulmonary capillaries in CTD-PH and hemodynamic indicators of PH, and to confirm the differences in cytokine profiles between CTD-PH and other PH, including IPAH, with IPAH.

Methods: Patients who underwent RHC for PH diagnosis at our hospital from 2015 to 2021 were included in the study. Serum was collected before and after pulmonary capillaries during right and left heart catheterization performed for hemodynamic analysis of PH, and cytokines were measured. TIMP-1, IL-21 MCP-1, IL-17, IL-12p70 and IL-6, which have been previously reported to be associated with the pathogenesis of CTD and PH, were included in the measurements in this study. TIMP-1, IL-21 were measured by ELISA (ABCAM UK). MCP-1, IL-17, IL-12p70 and IL-6 were measured by ELISA (Ellasimple plex USA). The relationship between the measured cytokine profiles and hemodynamic parameters was compared. Statistical analyses were performed using the Spearman's rank correlation coefficient and the Wilcoxon signed-rank test in JMP software v16.1.0 (SAS, USA).

Results: Eighty-one studies were performed on 56 patients who underwent right and left heart catheterization. Forty-seven were female and nine were male, with a mean age of 64.2 years. 33 were CTD patients, including 19 SSc, 10 MCTD, 2 SLE, and 2 SS, and 23 non-CTD patients, of which SSc had an age of 64.2 years. The mean mPAP was 29 +/- 9.3 mmHg in CTD-PH and 32 +/- 10 mmHg in non-CTD-PH, with no significant difference. In an analysis of all CTD-PH and non CTD-PH. Mean mPAP was 29 +/- 9.3 mmHg in CTD-PH and 32 +/- 10 mmHg in non-CTD-PH, with no significant difference. In an analysis focused on SSc, the differences were 75 years in the PH group and 10.8 years in the nonPH group. Three of the CTDs in which PH could not be diagnosed were using pulmonary vasodilators for treatment of DU. Ten cases in the CTD-PH group were receiving immunosuppressive therapy, whereas none of the non-CTD-PH could be diagnosed. The cytokine profile in pulmonary capillaries in CTD-PH and non-CTD-PH was analyzed. Mean mPAP was 29 +/- 9.3 mmHg in CTD-PH and 32 +/- 10 mmHg in non-CTD-PH, with no significant difference. In an analysis of all patients who were able to diagnose pulmonary hypertension, IL-6 and IL-12 levels in pulmonary capillaries were significantly associated with mPAP (p < 0.05). Furthermore, an association between IL-6 and IL-12 was found in all patients with CTD-PH, SSc-PH, and non-CTD-PH (p<0.05). In an analysis of CTD patients, TIMP-1 and IL-6 were markedly higher in SSc patients diagnosed with PH (TIMP-1: 134 +/- 42.8 vs 243 +/- 135, p<0.05, IL-6: 20.4 +/- 4.8 vs 21.2 +/- 8.0, p<0.05). In all groups examined this time, IL-17, IL-21, and MCP-1 were not significantly associated with severity of PH or with any of the hemodynamic parameter.

Conclusion: In the analysis of cytokines in pulmonary capillaries, IL-6 was found to be associated with hemodynamics in all PH patients, but TIMP-1 was found to be associated only with the PH pathogenesis of systemic scleroderma.

Background: The second COVID-19 vaccination in autoimmune disease (COVID-2) study [1] is an international, multicentre, self-reported e-survey designed to evaluate several facets covering COVID-19 infection and vaccination as well as validated patient-reported outcome measures (PROMs) in a variety of autoimmune inflammatory rheumatic diseases (AIDs), including systemic sclerosis (SSc). Detailed assessment of the health-related quality of life (HRQOL) and its drivers in patients with SSc is lacking.

Objectives: To assess physical and mental health in a global cohort of SSc patients in comparison with non-SSc autoimmune inflammatory rheumatic diseases (AIRDs), non-rheumatic AIDs (NRAIDs), and those without AIDs (controls) using Patient-Reported Outcome Measurement Information System (PROMIS) global health data from the COVAD-2 survey.

Methods: The COVAD-2 database was used to extract demographics, AID diagnosis, comorbidities, disease activity, current therapies, and PROMS. PROMIS global physical health (GPH), global mental health (GMH) scores, PROMIS physical function short form-10a (PROMIS PF-10a), pain visual analogue scale (VAS), and PROMIS Fatigue-4a scores were compared between SSc, non-SSc AIRDs, NRAIDs, and controls. Outcomes were also compared between patients with diffuse cutaneous SSc (dcSSc) vs limited cutaneous SSc (lcSSc). Multivariable regression analysis was performed to identify factors influencing GPH and GMH scores in SSc.

Results: A total of 10,502 complete responses from 276 SSc, 606 non-SSc AIRDs, 545 NRAIDs, and 3675 controls as of May 2022 were included in the analysis. Respondents with SSc were older (SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 55 (14) vs. 51 (15) vs. 45 (14) vs. 40 (14) years old, mean (SD), p < 0.001). Among patients with SSc, 129 (47%) had dcSSc and 147 (53%) had lcSSc. SSc patients reported a significantly higher prevalence of ILD [SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 30.4% vs. 5.5% vs. 1.5% vs. 0.2%, p < 0.001], and treatment with MMF [SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 26.4% vs. 9.5% vs. 1.1% vs. 0.0%, p < 0.001].
Patients with SSc had lower GPH and PROMIS PF-10a scores [SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 13 (11–15) vs. 13 (11–15) vs. 15 (13–17) vs. 17 (15–18), median (IQR), p < 0.001; 39 (33–46) vs. 39 (32–45) vs. 47 (40–50) vs. 49 (45–50), p < 0.001, respectively] and higher Pain VAS and PROMIS Fatigue-4a scores compared to those with NRAIDs or controls [SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 3 (2–5) vs. 3 (1–6) vs. 2 (0–4) vs. 0 (0–2), p < 0.001; 11 (8–14) vs. 11 (8–14) vs. 9 (7–13) vs. 7 (4–10), p < 0.001, respectively]. Patients with AIDs including SSc had lower GMH scores compared to controls [SSc vs. non-SSc AIRDs vs. NRAIDs vs. controls: 12.5 (10–15) vs. 13 (10–15) vs. 13 (11–16) vs. 15 (13–17), p < 0.001]. Among SSc patients, GPH, GMH, and PROMIS PF-10a scores were lower in dcSSc compared to lcSSC [dcSSc vs. lcSSC: 12 (10–14) vs. 14 (11–15), p < 0.001; 12 (10–14) vs. 13 (10–15), p < 0.001; 38 (30–43) vs. 41 (34–47), p < 0.001, respectively], Pain VAS and PROMIS Fatigue-4a scores were higher in dcSSc compared to lcSSC [4 (2–6) vs. 3 (1–5), p < 0.001; 12 (8–15) vs. 9 (8–13), p < 0.001, respectively]. The independent factors for lower GPH scores in SSc were older age, Asian ethnicity, glucocorticoid use, and higher pain and fatigue scales, while mental health disorders and higher pain and fatigue scales were independently associated with lower GMH scores.

Conclusion: In a global cohort, patient-reported physical and mental health were significantly worse in patients with SSc in comparison to those with non-SSc AIDs and without AIDs. Our findings support the critical need for more attention to patient's subjective experiences including pain and fatigue to improve the HROQOL in patients with SSc.

Background: The anti-Nucleolar Organizer Region 90 antibodies (NOR90) are rare antinuclear antibodies (ANA) identified in up to 6% of patients with systemic sclerosis (SSc). However, due to the small number of available studies, the clinical relevance of NOR90 in SSc remains uncertain.

Objectives: To analyze clinical associations of NOR90 in patients with SSc in a multicentric cohort.

Methods: Post-hoc, cross-sectional study of prospectively collected data from the European Scleroderma Trials and Research (EUSTAR) group database, with additional information on NOR90 provided by participating centers (EUSTAR project CP105). NOR90 was tested using immunocassays. Differences between patients with and without NOR90 were assessed using the U Mann-Whitney and the Chi-square test, and clinical associations were tested using regression models.

Results: Overall, 1318 patients with SSc were included (mean age 58.3±13.7 years, 81.3% female), of whom 44 (3.3%) were positive for NOR90, that were also positive for other SSc-specific antibodies: anti-topoisomerase I (20.3%), anti-centromere (42.9%), and anti-RNA polymerase III (12.5%). The demographic and clinical data of NOR90-positive and -negative patients are displayed in Table 1. There was no difference in the presence of severe organ manifestations including interstitial lung disease, pulmonary hypertension, and renal crisis, but NOR90-positive patients were more frequently female, had lower modified Rodnan skin score (mRSS), and lower prevalence of upper and lower gastrointestinal symptoms compared to NOR90-negative patients. In multivariable regression models adjusted for the presence of the most frequent SSc-specific antibodies, NOR90 remained significantly associated with lower mRSS and with less frequent gastrointestinal symptoms (Figure 1).

Conclusion: To the best of our knowledge, this is the largest SSc cohort tested for NOR90 so far. Apart from negative associations with skin fibrosis and GI symptoms, which should be analyzed in further studies, we did not find any significant association of NOR90 with SSc-associated organ/ system involvement.
However, these patients had a considerable prevalence of severe organ manifestations and should therefore be carefully evaluated.

Table 1. Demographic and clinical SSc-related data of NOR90-positive and -negative patients.

Data are presented as median (interquartile range) for the continuous variables and as number (percent) for the nominal ones. n = number of patients with positive results for the antibodies tested. N = total number of patients tested for the respective antibody. Significant p-values (p < 0.05) are marked in bold.

Keywords: Biomarkers, Cardiovascular disease, Systemic sclerosis

Methods: Carotid-femoral pulse wave velocity (cfPWV; gold standard of aortic stiffness), was examined in patients with SSc (ACR/EULAR classification) and healthy controls. Moreover, B-mode and Doppler sonography examinations of the common carotid arteries (CCA) were performed to assess plaque presence and/or possible abnormalities of carotid intima media thickness (cIMT), as well as resistance- and pulsatility-indices (RI, PI). Differences of these markers between patients and controls were statistically evaluated and subsequently controlled for the effects of possible confounding factors. Moreover, associations of the included CV and CVD surrogate parameters with clinical, laboratory and traditional CV risk factors were evaluated.

Results: 150 SSc-patients [84%♀, age 56.5 (50–65.3, IQR)] and 80 control subjects [86.3%♀, age 50.5 (35.2–57.8, IQR)] were recruited. cfPWV-values were statistically significantly higher in the patient group, compared to controls [8 m/s (6.86–9.44, IQR) vs. 6.85 (5.90–7.7, IQR), p<0.001], even after adjustment for the effect of confounding factors (p < 0.001). Similarly, cIMT [0.9 mm (0.65–1.9 mm)] was significantly higher in patients compared to controls [0.76 (0.60–1.08) vs. 0.73 (0.57–0.88, p<0.001)].

Figure 1. Association of NOR90 and SSc-criteria antibodies (ATA-ACA; RNP III) with the mRSS and gastrointestinal (GI) manifestations.

CCL24 is a novel target that was found to play a dual role in advancing pro-inflammatory and pro-fibrotic processes in systemic sclerosis (SSc). Previous studies reported that skin and serum CCL24 levels are elevated advancing pro-inflammatory and pro-fibrotic processes in systemic sclerosis (SSc). The present study reports that skin and serum CCL24 levels are elevated in SSc and that blocking of CCL24 was effective in preventing and attenuating experimental-induced fibrosis in murine models as well as interfering with endothelial cell activation. We show here that within the context of an observational cohort of unselected patients, CCL24 serum concentration is associated with the presence of DU as well as worse skin and lung fibrotic involvement, suggesting that this molecule may be involved in both vascular and fibrotic manifestations of SSc.

Raynaud’s microcirculation, musculoskeletal, digital ulcers, pulmonary involvement, cardiac involvement, hand function, calcification, skin involvement, Sjögren syndrome, and ii) general domains (fatigue, pain, cognition, sleep disorder).

Methods: A two-round international online Delphi exercise was conducted to enrich the list of instruments. Experts in iCSSc were asked to suggest additional items/outcome measures for the domains. Candidate clinician-reported outcomes (ClinROs) and performance outcomes (PerfOts) were selected during a two-day meeting utilizing a nominal group technique (NGT) comprising 3 patient research partners and 8 international experts. Patient research partners received specific training prior to the NGT meeting to become familiar with the domains, outcomes, and research processes.

Results: 100 experts were invited to the Delphi exercise and 71 provided answers for at least one round. Participants who provided answers in round 1 were invited to a second Delphi exercise, rating each item on scales (range: 1-9) for feasibility, face validity, content validity, and overall appropriateness for the CRISTAL Index. 5971 participants provided answers to at least one round. Items endorsed by more than 50% of the experts were included for discussion at the 2 day-NGT discussion. During the NGT meeting, for each iCSSc specific domain, the list of items selected during Delphi and their characteristics were presented and each voting member was asked to discuss the relevance of these items and to propose new items if important ones were considered missing. Voting members then ranked items from “most appropriate for the CRISTAL index” to “less appropriate.” At the end of each ranking, voting members were asked if they agreed with the ranking; 80% agreement was required to move to the next domain. Across the 10 iCSSc specific domains discussed, a total of 19 items (17 ClinROs and 2 PerfOts) were identified and retained as draft items for testing in the planned observational longitudinal cohort study (Table 1).

Conclusion: The results from the CRISTAL initiative are essential first steps towards the development of a composite index for iCSSc. The next steps will include selection of patient-reported outcomes (PROs) from the PROMIS item bank, existing data in the reported literature, and cognitive debriefing with patients, followed by a prospective case study to assess and validate the draft CRISTAL index.

DOI: 10.1136/annrheumdis-2023-eular.4633
These values were comparable to those of the ADEs reported in other SAIDs and HCIs. Patients with SSc reported higher frequency of difficulty in breathing than HCIs [OR=2.3 (1.03–5.1), p=0.042]. Individuals receiving Oxford/AstraZeneca reported more minor ADEs [OR=2.5 (1.0-6.0), p=0.049] whereas patients receiving Moderna were less likely to develop myalgia and body ache [OR=0.1 (0.02-1.0), p=0.047 and OR=0.2 (0.05-1.0), p=0.044 respectively]. Patients with diffuse cutaneous SSc experienced minor ADEs and specifically fatigue more frequently [OR=2.1 (1.1-4.4), p=0.035, and OR=3.8 (1.3-11.7), p=0.015] than those with limited cutaneous SSc. Self-reported active disease pre-vaccination did not confer any increased risk of vaccine ADEs in the adjusted analysis. Unlike our previous observations in myositis, autoimmune and non-autoimmune comorbidities did not affect the risk of delayed ADEs in SSc. SSc patients with concomitant myositis reported myalgia [OR=3.4 (1.1-10.7), p=0.035] more frequently, while those with thyroid disorders were more prone to report a higher frequency of joint pain [OR=5.5 (1.5-20.2), p<0.009] and dizziness [OR=5.9 (1.3-27.6), p=0.024] than patients with SSc alone. Patients with SSC-intestinal lung disease did not report increased frequency of ADEs.

Conclusion: A diagnosis of SSc did not confer a higher risk of delayed post COVID-19 vaccine-related ADEs than other SAIDs and HCIs. Diffuse cutaneous phenotype and certain co-existing autoimmune conditions including myositis and thyroid disease can increase the risk of minor ADEs. These patients may benefit from pre-vaccination counselling, close monitoring, and early initiation of appropriate care in the post COVID-19 vaccination period.

Continuous variables: Mean ± DE, Median (25-75%), Categorical variables: Frequency (%).

ILD: Interstitial Lung Disease, SSC: Systemic Sclerosis, RP: Raynaud's Phenomenon, mRSS: modified Rodnan Skin Score.

Background: Lung ultrasound (LUS) has proven useful to detect interstitial lung disease (ILD) among patients with systemic sclerosis (SSc) when compared to high-resolution computerized tomography (HRCT) as the gold standard; owing to its accessibility and innocuity it confers several advantages over the latter, which turns it into a potential valuable tool in clinical practice. Nevertheless, a key drawback is the lack of a standardized methodology to perform LUS.

Objectives: To evaluate diagnostic accuracy of LUS for ILD by comparing the systematic evaluation of 14 intercostal spaces (ICS) against 12 postero-basal ICS.

Methods: Patients with SSc were included according to the 2013 ACR/EULAR classification criteria of the Rheumatology clinic of the National Institute of Medical Sciences and Nutrition, reference hospital in Mexico City. Demographic, clinical, serological, and imaging variables were collected, followed by LUS assessment with the simultaneous scanning of 14 predetermined ICS and 12 postero-basal ICS. “B” lines (BL) and pleural abnormalities (PA) were documented for each ICS. HRCT was performed with a maximum 3 month-interval from the time of recruitment (before or after). Descriptive statistics for categorical and continuous variables was used. A bivariate analysis was undertaken to discriminate factors associated with the presence of ILD. A Pearson correlation test was carried out to compare findings between LUS and HRCT. Diagnostic accuracy was assessed through elaboration of ROC curves.

Results: We included 73 patients, with a median age of 54.5±15.1 years and 96.1% were women. Prevalence of ILD was 43.6%. Relevant baseline characteristics are shown in Table 1. Acknowledged risk factors for ILD were pulmonary hypertension (OR 6.27, CI 95% 1.75-22.4, p=0.005) and diffuse SSc (OR 6.17, CI 95% 1.92-19.76, p=0.002). The AUC were 0.87 (95% CI, 0.78-0.96), 0.94 (95% CI, 0.88-1.00) and 0.84 (95% CI, 0.74-0.94) for the evaluation of number of BL in 14 ICS, in 12 ICS and the number of ICS with PA (22 EIC), respectively.

Conclusion: Our study confirms the robustness of LUS as a tool for the detection of ILD through the quantification of BL and PA when using any of two different scanning protocols (14 and 12 ICS). However, more studies are required to elucidate the added value of pleural abnormalities identification for the diagnosis of ILD by LUS.

**SCLEROSIS: AN EUSTAR DATABASE ANALYSIS**

**METHODS:**

Patients diagnosed with systemic sclerosis (SSc) and registered in the EUSTAR database were included if they fulfilled the SSc classification criteria. Of these, 84.4% were female and mean age was 55.5±13.8 years. ACA was positive in 38% of patients and ATA in 32%; 4271 individuals (35%) were ever-smokers. Among never-smokers, 35% of patients was ATA positive, compared to 27% among ever-smokers (p <0.001). When stratifying for sex, this difference was accounted for by female patients: 34% of never-smoking females was ATA positive compared to 21% of ever-smoking women (p <0.001). In men, no statistically significant difference in ATA positivity was observed. Survival was significantly lower in ever-smokers than in never-smokers (46% vs 55%; log-rank test p=0.0032; Figure 1). In multivariable Cox regression analysis, ever-smoking was associated with mortality (HR 1.24; 95% CI 1.07 to 1.43). Evidence for an interaction between smoking status and sex was found (HR of interaction term 1.44, 95% CI 1.03 to 2.03). Cox proportional hazards models did not show an increased risk of developing ILD (HR 1.03; 95% CI 0.92 to 1.16) or cardiac involvement (HR 1.10; 95% CI 0.99 to 1.21), neither of functional worsening in ILD (HR 1.01; 95% CI 0.93 to 1.10) or cutaneous progression (HR 1.11; 95% CI 0.97 to 1.26) for ever-smokers.

**CONCLUSION:**

Our study in a large cohort of SSc patients from the EUSTAR registry confirms that ever-smoking is associated with lower prevalence of ATA positivity among female SSc patients. Our findings indicate that ever-smoking patients have a worse survival during follow-up, while no association between smoking and development of ILD, cardiac involvement or skin progression emerged.

**REAL-LIFE MULTICENTRIC NATIONAL OBSERVATIONAL STUDY OF THE USE OF NINTEDANIB IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**

**Keywords:** Real-world evidence, Safety, Systemic sclerosis
Background: Intersitial Lung Disease related to Systemic Sclerosis (ILD-SSc) is the first cause of mortality rate in this disease [1]. Significant functional decline in Forced vital capacity is one of the main prognostic factor in ILD-SSc and evaluation of the FCV is a key part of the follow-up of patient [2]. Nintedanib is a tyrosine kinase inhibitor that has been shown to be effective in ILD-SSc by significantly slowing decline in FCV [3]. To this day, no real-life data are available in ILD-SSc.

Objectives: Evaluation of efficacy and tolerance profile of Nintedanib in ILD-SSc patients in real life in France.

Methods: Multicentric data collection on call for observations through the GFRS, SNFMI and Orphalung. The data were obtained in an ambispective way with Data were available at 6 months after introduction of nintedanib in 60 patients.

Results: 60% of cases, and CT pattern was PINS in 85% of cases. Mean FVC was one of the major pronostic factor in ILD-SSc and evaluation (diarrhea in 5 cases, 1 significant weight loss) and including 1 death (cardiac arrest).

Methods: To evaluate RO7303509 safety, tolerability, pharmacokinetics, and pharmacodynamics of single ascending doses of RO7303509, an anti-TGFβ3 monoclonal antibody, in healthy volunteers.

Keywords: Systemic sclerosis, Randomized control trial, Biomarkers

Disclosure of Interests: None Declared.

In this study, we investigated IGU as a possible alternative treatment for SSc patients with ischemic DU. We constructed two cohorts from the Renji SSc registry. In the first cohort, SSc patients receiving IGU were observed prospectively with at least a 3-month follow-up to investigate the prevention of new ischemic DU occurrence. In the second cohort, we picked up all the DU patients with at least a 6-month follow-up to investigate the prevention of DU occurrence in a median follow-up of 39 weeks; further in the second DU cohort (Table 1), the protection of IGU was still true for new DU occurrence (adjusted RR = 0.25, 95% CI, 0.05-0.94, adjusted OR = 0.07, 95% CI, 0.01-0.49) (Figure 1).

Conclusion: Our study indicates IGU as a possible alternative treatment for SSc. Beyond expectation, this study for the first time describes IGU as preventative against ischemic DU occurrence and merits further investigation.

REFERENCES:

Methods: We constructed two cohorts from the Renji SSc registry. In the first cohort, SSc patients receiving IGU were observed prospectively with effectiveness and safety. In the second cohort, we picked up all the DU patients with at least a 3-month follow-up to investigate the prevention of IGU on ischemic DU.

Results: 1) IGU was a plausible alternative treatment for SSc with acceptable tolerance. 93.3% (21/23) of the SSc patients were disease worsening-free during IGU treatment (median follow-up: 61 weeks). 2) We unexpectedly discovered that IGU was protective against ischemic DU. Although with a limited patient number, 72.7% (8/11) of IGU-treated patients had no new DU occurrence in a median follow-up of 39 weeks; further in the second DU cohort (Table 1), the protection of IGU was still true for new DU occurrence (adjusted RR = 0.25, 95% CI, 0.05-0.94, adjusted OR = 0.07, 95% CI, 0.01-0.49) (Figure 1).

Conclusion: Our study indicates IGU as a possible alternative treatment for SSc. Beyond expectation, this study for the first time describes IGU as preventative against ischemic DU occurrence and merits further investigation.

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease leading to tissue atrophy, vascular damage and organ failures, and therefore causing severe disability. Coexistent autoimmune diseases are called overlap syndromes. Despite the distinct clinical picture[1], the extent of damage in SSc-overlap may be affected compared to pure-SSc.

Objectives: To identify differences in the time course and characteristics of damage between pure-SSc and SSc-overlap patients by evaluating the Scleroderma Clinical Trials Consortium-Damage Index (SCTC-DI)[2].

Methods: Single tertiary care centre observational study with 160 enrolled SSc patients. Eighty-eight patients (55%) had diffuse cutaneous SSc (dcSSc), 86% were female and median disease duration was 9 years/4.16. SSc-overlap was diagnosed based on the evaluation of the attending physicians. SCTC-DI was calculated. SCTC-DI score between 6-12 was considered as moderate and >12 points as severe damage. Damage profile of pure-SSc and SSc-overlap including subsets was compared.

Results: SSc-overlap was present in 24% of cases (n=39; 18 rheumatoid arthritis, 12 Sjögren, 12 myositis, 1 antiphospholipid syndrome). Age at enrolment and at disease onset, dcSSclimited cutaneous (iSSc) ratio, disease duration and gender distribution showed no difference between pure-SSc and SSc-overlap. Pure-SSc and SSc-overlap patients, including iSSc/dcSSc subset comparison had the same damage burden (Kruskal-Wallis p=0.05). Median/IQR SCTC-DI was similar in pure-SSc and SSc-overlap (97.14 and 96.13 respectively). Moderate damage was found in around 53% and severe damage in 28% of patients in both pure-SSc and SSc-overlap. Gastrointestinal, cardiopulmonary, cardiac, vascular and renal domains of SCTC-DI did not differ between SSc-overlap and pure-SSc, whereas proximal muscle weakness was more prevalent in SSc-overlap compared to pure-SSc. ILD was scored similarly frequently in pure-dcSSc and dcSSc-overlap (82% vs 66.7%, χ² p=0.05), however, it was also present in 65% of pure-iSSc and 60% of iSSc-overlap patients. Severe damage was more prevalent in SSc-overlap patients at early stage of SSc (p3 years duration, Fisher’s p=0.029) compared to pure-SSc. Early severe damage was more frequent in dcSSc-overlap compared to pure-dcSSc (Fisher’s p=0.042). Although in pure-SSc there were weak-to-moderate correlations between the SCTC-DI, age, and disease duration (Spearman’s ρc=.360-.498, p<0.001), no such associations were found in SSc-overlap patients. Differences in SCTC-DI items in pure-SSc and SSc-overlap are shown in Table 1.

Conclusion: SCTC-DI is a relevant tool to assess damage in SSc-overlap. In this cohort damage was not related to ageing and disease duration in SSc-overlap. Early dcSSc-overlap patients had higher risk to develop severe damage compared to early pure-dcSSc patients based on the SCTC-DI. Pulmonary damage was less frequent in SSc-overlap compared to pure-dcSSc, but similar in pure-dcSSc and dcSSc-overlap patients. As expected, musculoskeletal damage, especially proximal muscle weakness was present in a remarkable proportion of SSc-overlap patients.

LONGITUDINAL TRENDS IN MULTIMORBIDITY IN SYSTEMIC SCLEROSIS: RESULTS FROM AN INCIDENT POPULATION-BASED COHORT (1980-2018)

Keywords: Comorbidities, Systemic sclerosis, Epidemiology

A. Makol1, A. Karn1, S. Achenbach2, A. M. Hinze1, C. S. Crowson2. Mayo Clinic, Division of Rheumatology, Rochester, United States of America. Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America

Background: Systemic sclerosis (SSc) is a chronic inflammatory autoimmune disease characterized by vascular dysfunction and widespread internal organ fibrosis. Multimorbidity (MM), defined as the co-occurrence of two or more chronic conditions, can impact life expectancy, increase risk of hospitalizations, healthcare resource utilization and reduce quality of life. The accrual of MM in SSc and its determinants are not well studied.

Objectives: To assess the longitudinal trends of MM (i.e., the presence ≥2 morbidities) in an incident population-based cohort of patients with SSc vs. age- and sex-matched non-SSc comparators, and identify drivers of these trends.

Methods: A population-based cohort of incident physician diagnosed SSc patients between Jan 1, 1980, to Dec 31, 2018, was identified and compared to a 2:1 cohort of age- and sex-matched non-SSC comparators from the same population. Patients were followed until death, migration from the geographic area, or Dec 31, 2021. Data on 21 morbidities identified by the US Department of Health and Human Services (DHHS) and 13 morbidities included in the Charlson Comorbidity Index (CCI) was retrieved. Cumulative incidence of MM (MM2+ or substantial MM (MM5+; ≥ 5 morbidities) adjusting for the competing risk of death was estimated. Cox models adjusted for age, sex, index year and morbidities at index date were used to compare cases and comparators. Multivariable logistic regression models to predict morbidity type at event before index date were excluded from respective analyses.

Results: 85 patients with SSc were compared to 170 age- and sex-matched non-SSC comparators (mean age 55.4 ± 9.1% female, 90% white/non-Hispanic). At incidence/index date, a significantly higher prevalence of chronic obstructive pulmonary disease (COPD) (14% vs 4%, p=0.004), arthritis (33% vs 22%, p=0.054), peripheral vascular disease (40% vs 2%, p=0.001) and liver disease (5% vs 1%, p=0.04) were noted in patients with SSc. During a mean length of follow-up of 12.4 y (SD 9.8) for SSc & 15.5 y (SD 9.8) for comparators, the development of DHHS morbidities of heart failure (HF) (HR 2.90; 95% confidence interval [CI] 1.46-5.74), cardiac arrhythmia (hazard ratio [HR] 1.60; 95% CI 1.03-2.49), stroke (HR 2.08; 95% CI 1.04-4.16), chronic kidney disease (HR 1.86; 95% CI 1.09-3.18), and COPD (HR 2.02; 95% CI 1.09-3.80) were higher in SSc vs. non-SSC comparators. While osteoporosis (HR 2.03; 95% CI 1.18-3.51) was also higher in SSc patients, it did not reach statistical significance when adjusted for baseline morbidity count at index date. Similarly, CCI morbidities of HF (HR 2.86; 95% CI 1.51-5.42), peripheral vascular disease (HR 11.32; 95% CI 6.59-19.44), cerebrovascular disease (HR 2.43; 95% CI 1.28-4.72), chronic pulmonary disease (HR 3.82; 95% CI 2.18-6.69), moderate/severe renal disease (HR 3.02; 95% CI 1.30-6.91), and any liver disease (HR 1.81; 95% CI 1.32-6.92) were also significantly higher in SSc when compared to non-SSC comparators. The cumulative incidence of DHHS MM2+ during follow-up did not differ, but the development of DHHS MM5+ was significantly higher in SSc patients vs. comparators at 1.5% (44% vs 32%), 15% (52% vs 45%) and 20% (64% vs 58%) years of follow up (HR 1.58, 95% CI 1.09-2.31). The development of CCI-MM2+ (HR 4.56; 95% CI 3.00-6.93) was significantly higher among SSc patients but CCI-MM5+ was not statistically significant after adjusting for morbidity count at index (HR 1.65; 95% CI 0.80-3.43).

Conclusion: Multimorbidity is significantly more prevalent in patients with SSc and adds a substantial healthcare burden on these patients. Patients with SSc have a 1.5-3 fold higher risk of developing multiple cardiopulmonary morbidities. Patients who meet risk of developing peripheral vascular disease during longitudinal follow up than age- and sex-matched individuals without SSC. Multimorbidity assessment must be prioritized early in the disease course to reduce healthcare utilization and optimize long-term outcomes in this population.

INDUCTION OF REGULATORY T CELLS AND EFFICACY OF LOW DOSE INTERLEUKIN-2 IN SYSTEMIC SCLEROSIS: INTERVENTIONAL OPEN-LABEL PHASE 1–PHASE 2A STUDY

Keywords: Adaptive immunity, Investor initiated trial, Systemic sclerosis

F. Barde1, R. Lorenzon2,3, S. Riviere1, P. Caccoub4, M. Rosenzwajg2,3, C. Caciatorre1, A. Daguene-Ngueny1, O. Fain1, D. Klatzmann2,3, A. Meknian1,2, Hospital Saint-Antoine Ap-Hp, Internal Medicine, Paris, France; 2Sorbonne University, Faculté de Médecine, Paris, France; 3University Hospitals Pitié Salpêtrière - Charles Foix, Clinical Investigation Center for Biotherapies and Inflammation-Immunopathology-Biotherapy Department, Paris, France; 4University Hospitals Pitié Salpêtrière - Charles Foix, Department of Internal Medicine and Clinical Immunology, Paris, France; 5Hospital Saint-Antoine Ap-Hp, Pharmacy, Paris, France

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease, with impaired immune response, increased fibrosis, and endothelial dysfunction. (1,2) Regulatory T cells (Tregs), which are essential to prevent autoimmunity, showed a decreased frequency and impaired function during SSc. (3,4) Low-dose interleukin-2 (id-IL2) can expand and activate Tregs, but there are no data in SSc.

Objectives: We aimed to assess the in vivo biological efficacy of id-IL2 on Tregs and its safety in patients with SSc.

Methods: We performed an intervention prospective, open-label phase I-llla study in nine patients with SSc without severe organ involvement (eight patients with limited cutaneous subtype). This trial is a part of the TRANSREG study. All patients received 1 Million International Units (MIU)/day of IL2 for five days, followed by fortnightly injections for 6 months. The primary endpoint was the change in the relative Tregs blood concentration identified as CD25hiCD127lo/FoxP3+cells frequencies on day 8 among TCD4+ cells compared with baseline. Laboratory and clinical evaluations (modified Rodnan skin score (mRSS), Clinical Global Impression (CGI) activity and severity scale) were performed between day 8 and month 18.

Results: At day 8, the primary endpoint was reached with a 1.8 ± 0.5 fold increase of Tregs levels among TCD4+ lymphocytes (p=0.008). Changes in concentration of effector T cells (Teffs) and BCD19 cells were not statistically significant at day 8 and during maintenance period until month 6. Patients’ clinical assessments were stable throughout the follow-up with no modification on mRSS CGI activity and severity scale. Ld-IL2 was well tolerated, and no serious adverse events occurred.

Conclusion: Ld-IL2 at a dosage of 1 MIU/day for five consecutive days selectively activates and expands Tregs in SSc. Safety data were very encouraging. Phase II efficacy trials are needed to validate therapeutic potential of id-IL2.

**Norway**

The course of untreated SSc-ILD patients remains unknown. Systemic sclerosis (SSc). Current guidelines consider that some patients may require pharmacological treatment. To date, the characteristics and disease course of untreated SSc-ILD patients remain unknown.

**Methods:**

We included SSc patients from Zurich and Oslo who had a diagnosis of ILD on high-resolution computed tomography (HRCT) and available data on pulmonary function tests and treatment. The longitudinal study included patients with at least one follow-up visit. Patients were classified as treated if they had received a potential ILD modifying drug (immunosuppressive therapy or nintedanib). Treated and untreated patients were compared at baseline. ILD progression at any time point were compared with patients with no ILD modifying treatment during follow-up. In the untreated group, patients who had received a potential ILD modifying drug (immunosuppressive therapy or nintedanib). Treated and untreated patients were compared at baseline. ILD progression in the untreated group was defined as (i) decline in forced vital capacity (FVC) from baseline of ≥10% or (ii) decline in FVC of 5-9% associated with a decline in diffusing capacity for carbon monoxide (DLCO) of ≥15%, or (iii) start of any ILD modifying treatment during follow-up. In the untreated group, patients with ILD progression at any time point were compared with patients who had no ILD progression during follow-up. Multivariable logistic regression was performed to identify factors associated with no treatment of ILD at baseline in our cohort. Over mean 56 months of follow-up, 135/233 (58%) untreated SSc-ILD patients showed progression. Among them, 116 progressed on lung function parameters. Half of the patients (58) progressed at the first follow-up visit (mean 14 months). Male sex, diffuse cutaneous subtype, and extensive lung fibrosis were independently associated with lung progression during follow-up in untreated patients (Figure 1).

**Results:**

Untreated patients were more often women, had a longer disease duration, more frequently a limited cutaneous form, ant centromere antibodies and overall less extensive ILD. Particularly patients with anti-centromere antibodies and overall less extensive ILD. Conclusion: In the past, a large number of SSc-ILD have been untreated, particularly patients with anti-centromere antibodies and overall less extensive ILD. However, during a follow-up of nearly 5 years, contrary to common belief, about 60% of untreated patients showed progression of ILD. With the development of effective and safe therapies for SSc-ILD, our results support a change in clinical practice in selecting patients for treatment.

Distler1, M. Elhai1, University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland, Oslo University Hospital, Department of Rheumatology, Oslo, Norway, Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway

**Background:**Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). Current guidelines consider that some patients may require pharmacological treatment. To date, the characteristics and disease course of untreated SSc-ILD patients remain unknown.

**Objectives:** To describe disease characteristics and disease course in untreated SSc-ILD patients in two well characterized SSc-ILD cohorts.

**Methods:** We included SSc patients from Zurich and Oslo who had a diagnosis of ILD on high-resolution computed tomography (HRCT) and available data on pulmonary function tests and treatment. The longitudinal study included patients with at least one follow-up visit. Patients were classified as treated if they had received a potential ILD modifying drug (immunosuppressive therapy or nintedanib). Treated and untreated patients were compared at baseline. ILD progression in the untreated group was defined as (i) decline in forced vital capacity (FVC) from baseline of ≥10% or (ii) decline in FVC of 5-9% associated with a decline in diffusing capacity for carbon monoxide (DLCO) of ≥15%, or (iii) start of any ILD modifying treatment during follow-up. In the untreated group, patients with ILD progression at any time point were compared with patients who had no ILD progression during follow-up. Multivariable logistic regression was performed to identify factors associated with no treatment of ILD at baseline and factors associated with progression in untreated patients. Covariates were selected based on clinical experience and literature evidence.

**Results:** The cohort included 386 SSc-ILD patients. 301 (78%) had their first visit before 2016, 82 (21.5%) were males, mean age 57±14 years, mean disease duration 12±22 years, 120 (31%) had diffuse cutaneous SSc and 127/381 (33%) positive for anti-ScI70 antibodies. Of all, 290 (75%) were untreated at baseline. Untreated patients were more often women, had a longer disease duration, more frequently a limited cutaneous form, ant centromere antibodies and lower CRP levels. They had lower NYHA functional class, limited extent (<20%) of lung fibrosis, higher FVC (96±19 % vs. 81±22%), higher DLCO (69±20 % vs. 58±21) and better performances in the 6-minute walking test. In multivariable logistic regression, a less extensive disease on HRCT (OR: 3.71 [1.66-8.53], p=0.002) and ant centromere antibodies (OR: 5.16 [1.81-18.88], p=0.005) were independently associated with no treatment of ILD at baseline in our cohort.

**Conclusion:** In the past, a large number of SSc-ILD have been untreated, particularly patients with anti-centromere antibodies and overall less extensive ILD. However, during a follow-up of nearly 5 years, contrary to common belief, about 60% of untreated patients showed progression of ILD. With the development of effective and safe therapies for SSc-ILD, our results support a change in clinical practice in selecting patients for treatment.

FGF23 AND CARDIOVASCULAR STRUCTURE IN WOMEN WITH SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Biomarkers, Systemic sclerosis

A. Alvarez de Cienfuegos1, M. A. González-Gay2, N. Ortega5, Hospital Vega Baja, Rheumatology, Alicante, Spain; 2Fundacion Jimenez Diaz, Rheumatology, Madrid, Spain; 3Universidad de Granada, Facultad de Medicina, Granada, Spain

Background: Systemic sclerosis (SSc), an autoimmune disease characterized by fibrosis of the skin and various internal organs, is associated with cardiovascular abnormalities including pulmonary hypertension, atherosclerosis, right and left ventricular dysfunction, arrhythmias, conduction defects, pericardial disease, and valvular heart disease. Fibroblast growth factor-23 (FGF23) is a circulating regulator of phosphate and vitamin D metabolism and has been implicated as a putative pathogenic factor in cardiovascular disease. FGF23 has been associated with cardiac hypertrophy and reduced left ventricular ejection fraction among patients with chronic kidney disease and cardiovascular disorders.

Objectives: The aim of this study was to examine the possible association between serum FGF23 levels and echocardiographic abnormalities in women with SSc.

Methods: This cross-sectional study was performed in San Cecilio Hospital, Granada (Spain) from November 2017 to May 2019. Sixty-two women with SSc were enrolled in this study. All patients included in this study had normal serum creatinine (Cr) levels and met the 2013 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for SSc. Echocardiograms were performed at a single clinical site using Philips ie33 ultrasound machine with subjects in the left lateral decubitus position. Serum FGF23 was analyzed using ELISA.

Results: A total of 62 female patients were included in our study, with a mean (SD) age of 53 ± 10 years. The majority were Caucasian (90.5%). The mean disease duration was 8.8 ± 6.9 years. Forty-four (70.9%) patients had a limited form of the disease and 18 (29.1%) had a diffuse form. The mean left ventricular posterior wall thickness and left ventricular systolic diameter were 8.1±1.3mm and 25.3±4.8 mm, respectively. We found a statistically significant inverse relationship between serum FGF23 levels and echocardiographic abnormalities in women with SSc.

Conclusions: Our study found a statistically significant relationship between FGF23 and posterior wall thickness (r= -0.34; p= 0.03) and a statistically significant relationship between FGF23 and left ventricular systolic diameter (r= -0.5; p< 0.03) in women with SSc. Furthermore, in the linear regression model, lower FGF23 concentrations were associated with greater posterior wall thickness (r= 0.5; p= 0.03) in women with SSc.

THE HETEROGENEITY OF DEFINING SEVERITY, PROGRESSION AND OUTCOMES IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Outcome measures, Systemic sclerosis, Lungs

L. Petel tyska1,2, F. Bonomi3, C. Cannistrà3, E. Fiorentini3, S. Peretti3, S. Torracchi3, P. Bernardini3, C. Coccia3, R. De Luca3, A. Economou4, J. Levani2, M. Matucci-Cerinò4, A. Dosti2, C. Brunì1,3, 5University Hospital Zurich, University of Zurich, Dept Rheumatology, Zürich, Switzerland; 2Bogomolets National Medical University, Dept Internal Medicine #3, Kyiv, Ukraine; 3University of Florence - University Hospital Careggi, Dept Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 4San Raffaele Hospital, 4. Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Milano, Italy

Background: The course of systemic sclerosis associated interstitial lung disease (SSc-ILD) is highly variable. The SSc-ILD progression (SILPRO) project aims at developing a disease specific model to define SSc-ILD progression predicting long-term, severe SSc-ILD. The evaluation of currently used definitions of severity, progression and outcomes recorded in SSc-ILD represents the highly needed first step to achieve this aim.

Objectives: To identify definitions of progression, severity and outcomes related to SSc-ILD in the literature.

Methods: A systematic literature review was conducted according to PRISMA guidelines in Medline, EMBASE and the Cochrane Library up to 31/12/2021. Eligible papers included > 10 adult SSc patients, with ILD as primary target (at least one of population, exposure, outcome). Original papers in English were considered, while papers related to secondary lung involvement, ILD onset as an outcome or reviews were excluded. Two reviewers independently identified eligible studies and extracted data, including the abovementioned definitions used.

Results: We identified 299/8444 eligible papers, mostly reporting results of retrospective cohort studies (n=126, 42%), prospective cohort studies (n=120, 40%) and randomized clinical trials (n=24, 8%). A definition of SSc-ILD severity was included in 138 (46%) papers: it was based on high-resolution computed tomography (HRCT) data in 72 (52%) studies, on forced vital capacity (FVC) changes in 29 (21%), on combined FVC and carbon monoxide diffusing capacity (DLCO) changes in 14 (10%), on DLCO changes in 5 (4%) and combinations of these (6%); 6% of the studies included at least one of population, exposure, outcome. Original papers in English were considered, while papers related to secondary lung involvement, ILD onset as an outcome or reviews were excluded. Two reviewers independently identified eligible studies and extracted data, including the abovementioned definitions used.

Original papers in English were considered, while papers related to secondary lung involvement, ILD onset as an outcome or reviews were excluded. Two reviewers independently identified eligible studies and extracted data, including the abovementioned definitions used.

Sixty-one of 169 studies (36%) provided a definition of SSc-ILD "progression" referred to combined DLCO and FVC changes, 49 (29%) to FVC changes, 23 (14%) to DLCO changes, 18 (11%) to ILD extent on HRCT, 6 (4%) to combination of pulmonary function test (PFT), clinical signs and HRCT data, 5 (3%) to vital capacity decline, 5 (3%) to combination of PFT and HRCT data and 2 (1%) to other aspects (Table 1).

Conclusion: The studies reporting a definition of SSc-ILD "progression," "severity," and "outcome" show a large heterogeneity. These results emphasize the need for developing a standardized, consensus definition of severe SSc-ILD, to link a disease specific definition of progression as a surrogate outcome for clinical trials and clinical practice.

**A SINGLE CELL TRANSCRIPTOMIC ANALYSIS REVEALS A PRO-INFLAMMATORY PROFILE IN PERIPHERAL BLOOD CD14+ MONOCYTES OF SYSTEMIC SCLEROSIS PATIENTS**

**Keywords**: Biomarkers, Innate immunity, Systemic sclerosis

G. Villarroya-Martín1, M. Acosta-Hernández2, E. Carmona1, M. Kerick3, N. Ortge3, J. L. Callejas-Rubio4, S. Ng4, G. Mages4, S. Kliges5, S. Boerno5, B. Timmermann5, L. Bosini-Castillo6, J. Martín Ibanez7, Instituto de Parasitolatía y Biomedicina López Neyra - CSIC-, Granada, Spain; Instituto de Investigación Biosanitaria ibs.Granada, - Granada, Spain; Faculty of Medicine - University of Granada, Department of Medicine, Granada, Spain; Hospital Universitario Clínico San Cecilio, Department of Internal Medicine, Granada, Spain; Max Planck Institut für molekulare Genetik, Sequencing Core Facility, Berlin, Germany; Universidad de Granada, Departamento de Genetica, Granada, Spain

**Background**: Systemic sclerosis (SSc) is an immune-mediated disease, which affects mostly women over 50 years old. Recently, single cell mRNA sequencing techniques (scRNA-seq) have contributed to establish the relevance of different immune cell types in SSc. However, little is known about the diversity of the peripheral blood monocytes, which play a central role in the early inflammatory response and in the maintenance of inflammation in SSc.

**Objectives**: Our aim is to analyze the composition of the peripheral blood monocyte compartment of SSc patients and to establish disease and subtype specific transcriptomic profiles at the single cell level.

**Methods**: CD14+ monocytes were isolated from peripheral blood mononuclear cells (PBMC) of 8 SSc diagnosed women and 8 age matched unaffected females. All the patients were between 50 and 70 years old and classified as either limited cutaneous SSc (lcSSc) or diffuse cutaneous SSc (dcSSc). ScRNA-seq libraries were generated using the 10x Genomics Chromium platform and the Chromium Next Generation Single Cell S’Reagent Kits. After QC a total of 96,543 cells remained, with an average of ~7,000 cells per sample and 36,601 detected genes. Dimensionality reduction and cell clustering were performed using Scanpy, establishing 5,000 high variable genes and 20 principal components to implement the Leiden clustering algorithm.

**Results**: We identified 11 different clusters in the SSc combined analysis of the single cell transcriptomic data from both the SSc patients and the controls. Using known genes and cell markers, we identified classical monocytes, non-classical monocytes and intermediate monocytes, and a dendritic cell population (Figure 1). Non-classical monocyte populations were under-represented in SSc patients. Overall, we observed a proinflammatory profile in SSc CD14+ monocytes, which overexpressed genes related to the interferon signaling pathways, such as IRF4, IRF5, IFITM3 or IRF1, but also S100 family genes. This proinflammatory profile is especially enriched in the activated monocyte clusters, i.e. those with high expression of S100A8/S100A9 genes. Additionally, we identified the overexpression of TMEF1 and TMEF1 in IScSc patients compared to dcSSc patients and controls.

**Figure 1.** Monocyte subtype population in SSc. (A) UMAP visualization of monocyte CD14+ isolated from PBMCs sample of SSc and controls. (B) Proportion of cells of each monocyte subtype. (C) Outplot of gene and cell markers of monocyte subtype per cluster. The dot size indicates the number of cells expressing the gene in the cluster and the color the average of expression.

**Conclusion**: Our analysis of peripheral blood CD14+ monocytes in SSc patients showed an overrepresentation of non-classical monocytes and an increased interferon response compared to healthy controls. Moreover, we found subtype specific transcriptomic profiles, which suggested the possible use of monocyte subtypes as SSc biomarkers.

**LUNG FUNCTION ASSOCIATED WITH SUBCLINICAL MYOCARDIAL IMPAIRMENT IN SYSTEMIC SCLEROSIS: A CARDIAC MAGNETIC RESONANCE STUDY**

**Keywords**: Biomarkers, Systemic sclerosis, Cardiovascular disease

H. He1, X. Tong2, N. Ding3, J. Zhou4, C. Du5, Y. Wang5, D. Xu5, X. Zeng5, X. Zhao5, Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; Tsinghua University, School of Clinical Medicine. Beijing, China; Tsinghua University School of Medicine, Department of Biomedical Engineering. Beijing, China; Beijing Shijitan Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

**Background**: Systemic sclerosis (SSc) is an autoimmune disease and microvascularopathy is its major pathophysiological process. Patients with SSc usually have abnormal immune activation, neovascularization, and vascular remodeling. Progressive fibrosis and dysfunction will occur in multiple organs along with the progression of diseases, such as intestinal lung disease and cardiomyopathy [1]. Myocardial impairment is the major cause of death in patients with SSc [2]. Cardiac magnetic resonance (CMR) has been demonstrated to be an ideal non-invasive modality to assess myocardial pathology, particularly quantitative T1 [3]. However, CMR is not applicable for individuals with contraindications to MR examination.

**Objectives**: This study aimed to investigate the association between lung function and myocardial T1 values using cardiac magnetic resonance (CMR) in SSc patients without cardiovascular symptoms.

**Methods**: The SSc patients without cardiovascular symptoms and age- and sex-matched healthy subjects were recruited and underwent CMR examination to acquire CINE and T1 mapping images. Myocardial native T1 values and lung function were evaluated. Spearman's rank correlations and linear regression analyses were conducted to determine the association between lung function and myocardial native T1 values.

**Results**: Forty SSc patients (mean age 47.7±13.8 years, 35 females) and 13 (mean age 43.2±3.3 years, 10 females) healthy subjects were enrolled. SSc patients showed significantly higher native T1 value in myocardium compared to healthy subjects (1305±48.3 ms vs. 1273±73.5 ms, P=0.036). Diffusing capacity of lungs for carbon monoxide (DLCO) was significantly associated with myocardial native T1 value before (β=-0.958; 95%CI, -1.822 to -0.094; P=0.031) and after adjusted for confounding factors (β=-1.223; 95%CI, -2.155 to -0.291; P=0.012). Moderate-to-severe decrease of DLCO (DLCO<60%) was independently associated with myocardial native T1 value (β=31.189; 95%CI, 16.332 to 50.046; P=0.001). Figure 1 presents a typical case about myocardial native T1 value in a SSc patient (DLCO<60%) and an age- and sex-matched healthy subject.

**Conclusion**: Lung function is independently associated with myocardial native T1 values in SSc patients, particularly for moderate-to-severe decrease of DLCO, suggesting that lung function measurements might be a potential indicator for subclinical myocardial impairment in SSc patients. It is well established that chronic inflammation, the major pathophysiological process of SSc in early stage, persistently activates interstitial fibroblasts of multiple organs including lung and heart, leading to the irreversible fibrosis and subsequent decline of function [4].

**REFERENCES**

Background: Systemic sclerosis (SSc) is a severe, progressive multisystem rheumatic disease with high mortality, but without approved disease-modifying treatment to stop or reverse course of disease. Intravenous immunoglobulin G (IgG) may have a positive impact on SSc based upon available literature reports. However, to date, there have been no clinical trials evaluating subcutaneous IgG (SCIG) in SSc. In particular, the impact of pathologically altered skin in SSc on local safety and pharmacokinetics (PK) of SCIG has not been explored yet.

Objectives: The primary and secondary objectives of this trial (NCT04137224) included safety, including local infusion safety, and bioavailability of subcutaneous IgG (IgPro20) in adults with diffuse cutaneous SSc (dcSSc).

Methods: This was a randomized, open-label, crossover study. Adult subjects with dcSSc diagnosis within 5 years from first non-Raynaud's phenomenon and modified Rodnan Skin Score of 15-45 at screening were randomized 1:1 to sequence A (IgPro20, 20% normal human subcutaneous immunoglobulin followed by IgPro10, 10% normal human intravenous immunoglobulin) or sequence B (IgPro10 followed by IgPro20). Each subject was to complete two treatment periods (16 weeks each), with up to 40 weeks (including screening) study duration for an individual subject. Doses received were 0.5g/kg/week split over two sessions for IgPro20, and 2g/kg/4 weeks split over 2-5 days for IgPro10. The primary endpoint was safety of IgPro20, described as treatment-emergent adverse events (TEAEs) and changes in clinical observations.

Results: 27 subjects were randomized, with 13 subjects to sequence A and 14 subjects to sequence B. In total, 25 subjects completed the study. Of 27 treated subjects, 107 TEAEs occurred in 22 subjects (81.5%) over the 36-week study period, the majority of which were mild or moderate. The most common TEAEs (>10% of subjects) by preferred term (PT) were headache (12 events occurring in 6 subjects [22.2%]), COVID-19 (3 events occurring in 3 subjects [11.1%]), diarrhoea (3 events occurring in 3 subjects [11.1%]), and vomiting (3 events occurring in 3 subjects [11.1%]). A total of 10 serious AE (SAEs) were reported in 6 subjects (Viral infection, Chronic gastritis, Vomiting, Dehydration, Upper gastrointestinal haemorrhage, Chest pain, Myocardial infarction, Breast cancer, Intestinal hemorrhage). Among these, one subject experienced 2 SAEs (myocardial ischaemia & myocardial infarction) and was discontinued from study treatment. None of the SAEs were considered related to study treatment by the investigator, and no deaths were reported. For IgPro20, 14 infusion site reactions (ISRs) occurred in 5 subjects (19.2%), all were mild or moderate in severity. The most common ISRs were infusion site pain and infusion site swelling (3 events in 2 subjects each, 7.7%). In total, 868 IgPro20 infusions were performed, resulting in an overall ISR rate per infusion of 0.02, ie 2 ISRs per 100 infusions. No ISRs were reported for IgPro10. No clinically relevant trends in vital signs, body weight, clinical laboratory tests, electrocardiograms, or pulmonary function tests were observed. PK profiles and bioavailability in dcSSc subjects were similar to those observed in other approved indications such as Primary Immunodeficiency. Population relative bioavailability of IgPro20, based on dose-normalized, baseline-corrected AUClast was 0.761 (90% CI: 0.7033, 0.8232), ie 76.1% compared to IgPro10 (intravenous IgG).

Conclusion: The overall safety profiles of IgPro20 and IgPro10 in subjects with dcSSc were consistent with that in approved indications such as CIDP, including a relatively low ISR rate for IgPro20. PK profiles and bioavailability were also similar to other indications. This study indicates that subcutaneous administration of IgPro20 has acceptable safety, bioavailability and PK profiles in patients with dcSSc.

DOI: 10.1136/annrheumdis-2023-eular.25425
Background: Extracellular vesicles (EVs) are membrane-coated vesicles derived from virtually any cell type under different stimuli. Interstitial lung disease (ILD) is the leading cause of death in SSC. So far, only one study demonstrated elevated levels of EVs in patients with SSC-ILD [1], however the association between EVs and progressive ILD (pILD) was not previously investigated.

Objectives: To evaluate the concentration of different subpopulations of EVs in plasma from SSC patients in relation to the occurrence of pILD associated to SSC.

Methods: This was a prospective cohort study, including 59 SSC patients without any comorbidity (31 (52.5%) with ILD and 28 (47.5%) without). The median disease duration in ILD group was 3 years and 6 years in those without. ILD was defined either as X-ray positive findings or ground-glass opacification on HRCT. EVs were analyzed with flow cytometry after staining of platelet-poor plasma with fluorescent cell-specific monoclonal antibodies. The concentration of the following phosphatidylserine-positive EVs was analyzed at baseline: endothelial EVs (EEVs; CD144), platelet EVs (PEVs; CD42b*), leucocyte EVs (LEVs; CD45*), EVs expressing ICAM1 (CD54*), TF (CD142*) and HMGB1. The serum concentration of ICAM1, VEGF and IL6 were measured by ELISA. Lung functional tests were done every 6-12 months over a 3 years period of follow-up (FU). pILD was defined by the decline of forced vital capacity (FVC) from baseline visit of ≥10%, or an FVC decline of 5-9% along with a DLCO decline of >15% [2].

Results: An inverse relation was noticed in SSC patients between EVs and FVC (EEVs r=-0.3, p<0.05; LEVs r=-0.4, p<0.01; EVs ICAM1 r=-0.4, p<0.01; EVsTF r=-0.4, p<0.01; EVs HMGB1 r=-0.4, p<0.05). Significantly increased levels of VEGF, ICAM1, IL6, PEVs, and EVs expressing ICAM1, TF or HMGB1 were found in SSc ILD cohort compared to those without (p<0.05, respectively). There was only an association between ILD and PEVs (r=0.4, p<0.05). The correlation between EVs and progressive ILD (pILD) and non-progressive ILD (nILD) was not previously investigated.

Conclusions: In SSC patients, the levels of PEVs, EVs expressing ICAM1, VEGF, and HMGB1 were significantly higher in SSc ILD compared to those without (p<0.05, respectively). Moreover, the levels of PEVs, EVs expressing ICAM1 (AUC 0.9, p<0.001, respectively; TF, HMGB1, EEVs and LEVs (AUC 0.7, p<0.05, respectively) showed good validity in identifying pILD. There was only a positive correlation between VEGF and both EVs ICAM1 (r=0.8, p<0.01) and EVs HMGB1 (r=0.7, p<0.01) within pILD group. Applying Mi Cox R controlling for VEGF, EEVs ICAM1 were confirmed independently significantly associated with pILD (OR 1.1, 95% CI 1.02-1.1).

POS1282
CARDIAC MAGNETIC RESONANCE IN ANTI-SYNTHESE SYNDROME: THE ADDITIONAL VALUE OF T2 MAPPING TO DETECT MYOCARDITIS

Keywords: Heart, Imaging, Cardiovascular disease

G. De Luca1, C. Campochiaro1, A. Ferlito2, G. Peretto2, A. Palmisano3, A. Esposito1, L. Danesi1,1Vita-Salute San Raffaele University & San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy & Rare Diseases, Milan, Italy; 2Vita-Salute San Raffaele University & San Raffaele Hospital, Anthropology, Milan, Italy; 3Vita-Salute San Raffaele University & San Raffaele Hospital, Radiology - CMR Unit, Milan, Italy

Background: Myocarditis can be a subtle and underdiagnosed manifestation of anti-synthetase syndrome (ASS), and its occurrence is associated with a poor prognosis. Cardiac magnetic resonance (CMR) is the diagnostic modality of choice for the non-invasive diagnosis of myocarditis, which historically relies on the 2009 Lake Louise Criteria (LLC) [1]. LLC, however, have a low diagnostic accuracy in patients with coexisting myositis.

Objectives: To investigate the performance of the mapping techniques included in the revised LLC [2] for the identification of ASS myocarditis.

Methods: CMR data (right and left ventricular function and morphology, early and late gadolinium enhancement [LGE], T2 ratio, and T1 mapping, extracellular volume [ECV] and T2 mapping) of ASS patients diagnosed with myocarditis were reviewed. Myocarditis was clinically defined by the presence of signs and/or symptoms of heart involvement with increased high-signal tropinin T (hs-TnT) and/or NT-proBNP serum levels and at least an abnormality at 24h ECG Holter and/or echocardiography and/or CMR.

Results: We identified 11 patients (mean age 58 ±13 years; females 45%; anti-Jo1 55%, anti-PL-7 27%) with ASS myocarditis. Dyspnea was the most frequently reported symptom (64%), 4 patients (36%) had echocardiographic abnormalities, while 24-hour-ECG Holter was normal in all patients. At baseline, troponin T levels were raised in all but 1 patient (mean value 461 ±351 ng/L), while NT-proBNP levels were raised in 45% of patients (mean value 1802 ±1484 pg/mL). All patients had at least one CMR abnormality: increased ECV in all patients, LGE in 10% (91%), and T2 mapping >50ms in 10% (91%). Median T1 and T2 mapping were 1079 [range 906-1172] ms and 53.2 [range 48.8-57.4] ms, respectively. No significant statistical correlation emerged between CMR parameters (T1 mapping, T2 mapping and ECV) and disease parameters (troponin, NTproBNP, CPK levels and inflammatory markers). Six patients satisfied the 2009 LLC, the 2018 LLC with the new criteria including T2 mapping, the sensitivity improved from 54% to 91%.

Conclusion: The CMR mapping techniques improve the sensitivity to detect myocardial inflammation in patients with ASS-related heart involvement. The evaluation of T2 mapping increases diagnostic accuracy for the recognition of myocardial inflammation in ASS and should be always performed in ASS patients with suspected myocarditis.

Background: Heart involvement is one of the leading causes of death in systemic sclerosis (SSc). Cardiac manifestations are heterogeneous. In particular, prevalence of SSc-related cardiopathy is poorly known due to a lack of consensus in its definition.

Objectives: Our objective was to investigate the prevalence and prognosis burden of the different heart diseases in a nationwide cohort of patients with SSc.

Methods: We used data from a national multicentric prospective study using the French SSc national database. We described the characteristics of 3 different types of heart involvement: SSc-related cardiopathy, pulmonary arterial hypertension and ischaemic heart disease. We analyzed overall survival and survival according to the heart disease. Focusing on SSc-related cardiopathy, we aimed to determine its incidence and risk factors.

Results: Over the 3528 patients with SSc available for baseline analyses 312 (10.9%) had SSc-related cardiopathy at baseline. They tended to have a diffuse SSc subtype more frequently, had more severe clinical features, and presented more cardiovascular risk factors. From the 1646 patients available for follow-up analysis, SSc-related cardiopathy was associated with an increased risk of death. No significant difference of overall survival was found between SSc-related cardiopathy and the other 2 cardiovascular risk factors. Concerning survival analysis, 98 patients developed SSc-related cardiopathy at 5 years (5-year event-rate: 11.15% [9.01; 13.23]). Regarding reduced LVEF < 50% and left ventricular diastolic dysfunction, the 5-year event-rate were 2.49% [CI95%: 1.13; 3.83] and 5.84% [CI95%: 4.02; 7.62], respectively. The pericarditis cumulative incidence at 5 years was 3% [CI95%: 1.91; 4.08]. Diffuse SSc subtype was a risk factor of SSc-related cardiopathy (adjusted HR: 1.79 [CI95%: 1.06; 3.02], p = 0.03). Female sex was associated with less diastolic dysfunction incidence (adjusted HR: 0.39 [CI95%: 0.24; 0.63], p = 0.0001).

Conclusion: Our results further describe at a large scale the incidence and prognostic burden of SSc-related cardiopathy, with gender and diffuse SSc subtype as risk factors. Further analyses should assess the potential impact of treatment on these various cardiac outcomes.

References:

Results: Forty-two SSc patients underwent cardiac magnetic resonance after developing symptoms (dyspnea, atypical angor, palpitations; 43%), elevated cardiac enzymes (55%), or Holter ECG alterations (38%). Myocardiopathy was detected in 29/42 patients (69%; 29/16, 9.2%). Early disease was significantly more frequent in patients with myocardiopathy (17/29, 59%; OR 7.8, 95% CI 1.45-

Background: Myocardial involvement is frequently asymptomatic at the early stages in systemic sclerosis (SSc) but accounts for one-third of SSc-related deaths [1]. First-line screening tools include cardiac enzymes, Holter ECG, and echocardiography [2,3], while the diagnosis relies largely on cardiac magnetic resonance [4], assessing myocardial inflammation and fibrosis [5]. The prevalence of SSc myocardiopathy and the associated factors are poorly defined [2].

Conclusion: We report a relevant overall prevalence of myocardiopathy in a cohort of SSc patients, similar pulmonary hypertension, affecting one third of patients with early SSc, especially with anti-Scl70. Conversely, a delayed onset of myocardiopathy was associated with ACA. Among other predictors, higher serum troponins and Holter ECG alterations, especially PVC, were significantly associated to myocardiopathy. As the early suspicion and diag-

J. Vos1, J. Lemmers2, S. Elmessoudi1, M. Snoeren3, A. Van Dijk4, T. Duijnhouwer1, L. Rodwell4, S. Van Leuven2, M. Post5, M. Vonk2, R. Nijveldt1. 1Radboud University Medical Center, Cardiology, Nijmegen, Netherlands; 2Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 3Radboud University Medical Center, Radiology, Nijmegen, Netherlands; 4Radboud University Medical Center, Health Evidence, Nijmegen, Netherlands; 5St. Antonius Hospital, Cardiology, Nieuwegein, Netherlands

Background: Systemic sclerosis (SSc) is characterized by vasculopathy, fibrosis, and inflammation, and carries one of the worst prognoses if patients also develop pulmonary arterial hypertension (PAH). Although PAH is a known prognostic factor, SSc-PAH patients demonstrate disproportionately high mortality, presumably due to cardiac involvement [1].

Objectives: To investigate the relation between cardiac involvement as revealed by Cardiovascular Magnetic Resonance (CMR) and systemic microvascular disease severity as measured with nailfold capillaromicroscopy (NCM) in SSc-PAH patients, compared to idiopathic PAH (IPAH) patients.

Methods: SSc-PAH and IPAH patients underwent CMR, transthoracic echocardiography (TTE), and NCM with post-occlusive reactivity hyperemia (PORH) testing on the same day [2-4]. CMR imaging included T2 mapping, native and postcontrast T1 mapping, to assess edema and fibrosis, and adenosine-stress perfusion imaging to measure the relative myocardial upslope (to determine microvascular coronary perfusion). Measures of peripheral microvascular function were related to CMR indices of edema, fibrosis and myocardial perfusion.

Results: SSc-PAH patients (n=20) had higher extracellular volume fraction (ECV) and T2 values than IPAH patients (n=5), and lower nailfold capillary density (NCD) and reduced capillary recruitment after PORH. NCD correlated with native T1, ECV, and T2 values (r=0.431, -0.443, and -0.464, respectively, p<0.05 for all), and with markers of diastolic dysfunction on echocardiography. Furthermore, PORH-testing, but not NCD, correlated with the relative myocardial upslope by stress CMR (r=0.421, p<0.05) (Table 1).

Conclusion: SSc-PAH patients showed higher markers of cardiac fibrosis and inflammation, compared to IPAH patients. These markers correlated well with peripheral microvascular dysfunction, suggesting that SSc-driven inflammation and vasculopathy concurrently affect peripheral microcirculation and the heart. This may contribute to the disproportionately high mortality in SSc-PAH patients.

Background: Systemic sclerosis (SSc) is a connective tissue disease with multiple organ manifestations including cardiac involvement. Several studies have reported arrhythmias and conduction defects to be frequent in patients with SSc, however with considerable limitations such as the lack of comparison group or of stratified analyses by arrhythmia subtypes in some studies in addition to some study populations being highly selected from tertiary care centres.

Objectives: To explore the incidence of cardiac arrhythmias and its different subtypes in an unselected national cohort of patients with SSc compared to a matched cohort from the general population in Sweden.

Methods: We used nationwide Swedish registers to identify patients with incident SSc diagnosed between 2004 and 2015 in addition to comparators from the general population (1:5), matched on sex, birth year and residential area. We excluded those with a history of arrhythmia prior to start of follow-up. The primary outcome was the first ICD-coded visit indicating arrhythmia. Follow-up started from the date of SSc diagnosis, the same date was assigned to the respective comparators, until the primary outcome, death, emigration, or the end of 2016. We estimated the incidence rate of arrhythmias overall and stratified by subtype of arrhythmia in both patients with SSc and their comparators. We estimated incidence rate ratios (IRR) using poisson regression models and time-varying hazard ratios (HRs) using flexible parametric models.

Results: We identified 1049 patients with SSc and 5147 matched comparators with no prior history of arrhythmia. The median follow-up was 4.7 years in patients with SSc and 5.8 years for the comparators. The incidence rate of arrhythmias overall was 216.5 per 10,000 person-years (95% CI 179.8-258.5) in patients with SSc and 106.6 (95% CI 95.5-118.7) in the comparators corresponding to IRR of 2.0 (95% CI 1.7-2.5). Table 1 demonstrates the incidence rates and IRRs stratified by arrhythmia subtypes. The HR of arrhythmia overall in patients with SSc compared to the comparators decreased gradually during follow-up; 3.0 (95% CI 2.2-4.1) at the end of the first year of follow-up, 1.9 (95% CI 1.4-2.5) at the end of the fifth year of follow-up, and 1.3 (95% CI 0.8-2.3) at the end of the 10th year of follow-up.

Conclusion: Patients with SSc have higher incidence rate of arrhythmia overall compared with matched comparators from the general population.

Table 1: Incidence rates of arrhythmias in patients with SSc and in general population comparators, overall and stratified by arrhythmia subtypes. Incidence rate ratios are estimated using poisson regression models.

DOI: 10.1136/annrheumdis-2023-eular.2861
Methods: We used a simplified directed acyclic graph (DAG) of the postulated causal pathways for simulation (Figure 1). The 8 nodes, some representing groups of variables, were: non-specific predisposing factors; SSc-specific predisposing factors; comorbidities; SSc; FVC; HAQ; selection; and non-missing data. Arcs (arrows) representing directed causal effects were drawn from earlier nodes in the pathway to each subsequent node. In statistical software [1] we drew the DAG and entered coefficients for each arc, informed in part by baseline descriptive data from ~17k patients in the EUSTAR registry (clinical project 96). We set a 'true' coefficient for the focal relationship between FVC and HAQ of -0.3; negative so that lower FVC would lead to higher HAQ. All variables were simulated to be continuous and all relationships were linear. We split the SSc variable at the 0.9997th and 0.9999th centiles to simulate three groups: no SSc, limited and diffuse SSc. We split the selection variable at the 1st or 3rd quartile to simulate weak selection (e.g. into the registry), or strong selection (e.g. into a clinical trial). We split the non-missing data variable at the 86th centile to simulate data missing not at random. We simulated 1000 datasets of N=76000000.

Results: Descriptive data from EUSTAR suggested that those with HAQ available were younger with shorter disease duration, higher rates of interstitial lung disease and lower rates of elevated systolic pulmonary pressure. In the simulated data, a regression model including all confounders (HAQ = FVC + SSc + Comorbidity + Specific + Non-specific) correctly estimated the coefficient for FVC in the population (median [95% simulation interval] -0.307 [-0.307 to -0.307]). Omitting confounders overestimated the coefficient by 5% to 28% depending which nodes were omitted. Including confounders, but sub-setting to include SSc only (-0.19 [-0.21 to -0.18]), to mimic weak (-0.18 [-0.20 to -0.17]) or strong selection (-0.17 [-0.20 to -0.15]) or to mimic both weak selection and missing data (-0.14 [-0.19 to -0.10]) underestimated the coefficient by 37% to 53%, although the model was correctly specified.

Conclusion: This simulation study illustrates the importance of considering the underlying causal pathways and potential biases when characterising relationships between key variables in observational datasets. Naïve analyses which do not account for confounding, selection bias and missing data can give misleading results. In this simplified example we might have concluded, in error, that the relationship between FVC and HAQ was weaker or stronger than it truly was. As we generated our own data, we knew the 'true' coefficient and the underlying data generating mechanisms. However, in practice we would know neither, but causal inference methods provide transparency as to the assumptions made during analysis and help identify any areas of concern. Careful consideration of the causal pathways to derive the appropriate model, and efforts to mitigate or remove sources of bias via study design and analysis, can improve accuracy and increase confidence in conclusions.

POS1299 MACHINE LEARNING ALGORITHM AS A USEFUL TOOL IN THE GREY AREA OF CARDIOPULMONARY MORTALITY IN SYSTEMIC SCLEROSIS

Keywords: Artificial intelligence, Cardiovascular disease, Systemic sclerosis

P. G. Cerasulo1, E. De Lorenzo1,2, G. Natale1, L. Verardi1, G. Alonzi1, S. Fiore1, A. Zoli1, S. Di Muro1, M. A. D’agostino1, S. L. Bosello1. 1Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy, 2Rheumatology Department, Roma, Italy; 2Sclerodema Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Rheumatology Department, Leeds, United Kingdom

Background: Prognosis of systemic sclerosis (SSc) patients is related to the presence of major internal organ involvement and specific autoantibody positivity. Cardiopulmonary complications are the leading cause of death in patients with SSc.

Objectives: The objective of the study is to evaluate the ability of an artificial intelligence algorithm based on laboratory and functional variables associated to SSc cardio-pulmonary involvement to predict the 5-year related mortality.

Methods: Laboratory and functional parameters of cardiopulmonary involvement of SSc patients symptomatic for dyspnoea, palpitations, or chest pain were recorded. Forced vital capacity (FVC), alveolar diffusion of CO (DLco), serum troponin, NT-proBNP, cardiac ejection fraction (EF) and pulmonary arterial systolic pressure (PAPs) were used for clustering by a partition around medoids (PAM) algorithm. The resulting clusters were compared for 5-year mortality due to SSc cardio-pulmonary causes.

Results: 216 patients were enrolled, aged 54.5±14.4 years, and with a disease duration of 7±7 years. The 12% of patients were male, 41% had a diffuse cutaneous disease, 45% were anti-ScI70 positive. With specific reference to cardiopulmonary involvement, 50% of patients had pulmonary fibrosis at HRCT, 15% pulmonary arterial hypertension, 16% a EF <55%, 11% increased levels of troponin, and 42% elevated NT-proBNP levels. During follow-up, 28 patients (12%) died because of causes related to cardiac-pulmonary involvement. The machine learning algorithm identified two different groups according to prognosis (p<0.001) with a 5-year mortality of 15% and 0.8%. Patients with higher mortality were characterized by lower FVC values and higher NT-proBNP than controls. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of outcomes between patients with SSc.

Conclusion: A nationwide population-based cohort study revealed an association between SSc and increased risk of MI and stroke. Therefore, monitoring and preventive measure for the cardiovascular diseases in patients with SSc are required.

POS1291 PREDICTION OF MORTALITY IN SSc-ILD DEPENDS ON DEFINITION OF ILD PROGRESSION

Keywords: Lungs, Systemic sclerosis, Prognostic factors

A. M. Hoffmann-Vold1,2, L. Petelytska1, H. Fretheim1, I. Baru1, M. O. Becker1, H. J. Bjørkaker1, C. Brunborg1, C. Bruni2, P. P. Diep3, R. Dobrota4, M. Durheim4, M. Elahi5, S. Jordan5, E. Langballe1, O. Midvedt1, C. Mihai6, O. Molberg7, O. Dieterle8, 1Oslo University Hospital, Rheumatology; Oslo, Norway; 2University Hospital Zurich, University of Zurich, Rheumatology, Zurich, Switzerland; 3Hospital of Southern Norway, Rheumatology, Kristiansand, Norway; 4Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway; 5Oslo University Hospital, Respiratory Medicine, Oslo, Norway

Background: Progression of interstitial lung disease (ILD) is a candidate for long-term mortality in patients with systemic sclerosis (SSc). Different definitions of progression have been proposed. Declining lung function is often used, whereas others include composite definitions such as the 2022 ATS/ERS/JRS/ALAT guideline criteria for progressive pulmonary fibrosis (PPF) and the INBUILD criteria for progressive fibrosing ILD (PF-ILD). These different definitions have not been compared in SSc-ILD.

Objectives: To estimate the prevalence of ILD progression applying different definitions and test their performance of predicting mortality.

Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT and serial assessments of disease progression defined as:

(A) Absolute FVC decline ≥5% over 12 months

(B) PFF guideline criteria with ≥2/3 criteria present over 12 months of (1) worsening of respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) disease progression on HRCT

(C) INBUILD PF-ILD criteria within 24 months with (1) FVC decline ≥10%, (2) FVC decline >5%–<10% and worsening of respiratory symptoms or increased lung fibrosis on HRCT, or (3) worsening of respiratory symptoms and increased lung fibrosis.

We assessed the prevalence of ILD progression using these competing definitions and applied multinivariable regression models (with hazards ratios (HR) and 95%CI) adjusted for known risk factors for mortality and compared the performance using Harrel’s c-index.

Results: In total, 231 SSc-ILD patients from Oslo and Zurich were included, with 71 (31%) showing FVC decline >5%, 43 (19%) fulfilling the PPF guideline and 89 (39%) the INBUILD PF-ILD criteria. Most progressive patients fulfilled ≥1 of definitions of progression with 107 (55%) with ≥2/3, 114 (54%) with ≥1 and none (0%) did not progress (Figure 1). Patient characteristics did not differ between the definitions, except for more extensive ILD and ground glass on HRCT and more frequent oxygen desaturation among those fulfilling the PPF criteria (Table 1). The number of deaths by age, sex, disease duration, SSc subtype, extent of lung fibrosis, baseline FVC and treatment using FVC decline≥5% (HR 1.97, 95%CI 1.03-3.81)

Disclosure of Interests: None declared, Francesco Del Galdo Speakers bureau: Boehringer Ingelheim, Michelle Wilson: None declared, Mark Gilthorpe: None declared, Jannsen, AstraZeneca, Consultant of: AstraZeneca, Boehringer Ingelheim, Capella, Chemomab, Kymab, Jannsen, Mitsubishi-Tanabe. POS1290 INCREASED RISK OF MYOCARDIAL INFARCTION AND STROKE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A NATIONWIDE COHORT STUDY

Keywords: Epidemiology, Systemic sclerosis, Cardiovascular disease

Y. Eun1, K. D. Han1, J. K. Ahn1. 1Kangbuk Samsung Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Soongnai University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)

Background: Previous studies have suggested a link between systemic sclerosis (SSc) and cardiovascular disease, but large-scale data are still lacking due to the nature of rare autoimmune diseases.

Objectives: We aimed to compare the incidence of myocardial infarction (MI) and stroke in patients with SSc and age- and sex-matched controls in a nationwide population-based cohort in Korea.

Methods: We included patients with SSc defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1.5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were MI and stroke.

We assessed the prevalence of ILD progression using these competing definitions and applied multinivariable regression models (with hazards ratios (HR) and 95%CI) adjusted for known risk factors for mortality and compared the performance using Harrel’s c-index.

Results: In total, 231 SSc-ILD patients from Oslo and Zurich were included, with 71 (31%) showing FVC decline >5%, 43 (19%) fulfilling the PPF guideline and 89 (39%) the INBUILD PF-ILD criteria. Most progressive patients fulfilled ≥1 of definitions of progression with 107 (55%) with ≥2/3, 114 (54%) with ≥1 and none (0%) did not progress (Figure 1). Patient characteristics did not differ between the definitions, except for more extensive ILD and ground glass on HRCT and more frequent oxygen desaturation among those fulfilling the PPF criteria (Table 1). The number of deaths by age, sex, disease duration, SSc subtype, extent of lung fibrosis, baseline FVC and treatment using FVC decline≥5% (HR 1.97, 95%CI 1.03-3.81)
95%CI p=0.020; c-index 0.7331), PPF guideline (HR1 .42, 0.79-1.84 95%CI; p=0.231; c-index=0.7156) and INBUILD PF-ILD (HR 2.38, 1.40-4.04 95%CI: p<0.001; c-index=0.7338). The models discriminating ability was not significantly different (p=0.138).

**Conclusion:** The prevalence of ILD progression varies depending on which definition was applied. FVC decline alone and PF-ILD criteria predicted mortality significantly but not the 2022 PPF guideline criteria.

**DOI:** 10.1136/annrheumdis-2023-eular.3181
Background: Patients with systemic sclerosis (SSc) are at risk of developing pulmonary hypertension (PH) of different etiologies. Two-dimensional and Doppler echocardiography is the reference screening tool and it is recommended yearly on patients undergoing screening for PH and who were followed-up regularly at a third-level centre of reference for SSc.

Patients underwent both the baseline echocardiographic examinations and at least one echocardiographic examination during follow-up in the referral centre. Standard 2-D and Doppler echocardiography was performed with a Vivid 7 or Vivid E9 ultrasound system (GE Medical Systems, Norway); images and clips were saved for offline analysis on a GE workstation (EchoPAC PC SW). Clinical, laboratory and radiographical parameters, standard in the care of SSc, such as presence of Interstitial lung disease, left-heart disease (LHD), pulmonary function tests and biomarkers as BNP were concomitantly recorded for each patient. The DETECT step 1 and 2 values were calculated according to the 2013 ACR/EULAR SSc classification criteria [1], undergoing screening for PH and who were followed-up regularly at a third-level centre of reference for SSc.

All patients underwent both the baseline echocardiographic examinations and at least one echocardiographic examination during follow-up in the referral centre. Standard 2-D and Doppler echocardiography was performed with a Vivid 7 or Vivid E9 ultrasound system (GE Medical Systems, Norway); images and clips were saved for offline analysis on a GE workstation (EchoPAC PC SW). Clinical, laboratory and radiographical parameters, standard in the care of SSc, such as presence of Interstitial lung disease, left-heart disease (LHD), pulmonary function tests and biomarkers as BNP were concomitantly recorded for each patient. The DETECT step 1 and 2 values were calculated according to Coghlan JG et al [2]. When indicated according to guidelines, right heart catheterization to diagnose PH was performed. Statistical analysis was performed using SPSS by IBM for mac (v.13).

Results: The study enrolled 93 females and 20 males, mean age was 58±13 yrs, median disease duration was 88 months (IQR 42-168); 86 (76%) patients had limited cutaneous involvement, 21 had diffuse disease (18.6%) and 5 (4.4%) had no skin involvement at all. At baseline, antinuclear antibody and antiproteinase antibodies were positive in 38 (33.6%) and in 35 (31%) patients respectively. A clinically significant ILD was present in 17 (15%) of patients of the cohort at baseline. During follow-up (44±24 months), 10 patients were diagnosed with PH (overall incidence of 8.4%) which was classified as Group 1 PH in 4 cases (40%), Group 2 PH in 1 case (10%) in Group 3 PH in 5 cases (50%). Baseline standard echocardiographic parameters including the estimated sPAP and DETECT scores for step 1 and step 2 were similar in patients who developed PH and those who did not. However, peak longitudinal right ventricular (RV) strain (RVPLS) values were significantly lower in patients who subsequently developed PH (42,13 ± 12,21 vs 33,57 ± 11,52, p=0,019).

Conclusion: An sSSc cohort of patients at risk of developing PH, adding the evaluation of 2D-Speckle-tracking echocardiography (STE) analysis, and in particular PLS of the RV, might intercept at an early stage an alteration of the right heart to abnormally adapt to the pulmonary vasculature overload in different extrinsic pathological settings (ILD, LHD) and also in the presence of an intrinsic pulmonary vasculopathy.

Results: Our cohort consisted of 87 SSc patients, of which 64 (73.6%) were women, with a mean age at disease onset of 54.5 years (SD ± 19) and a median disease duration of 4.0 years (IQR 8.3). The median dp-ucMGP level at baseline was 634 pmol/L (IQR 391), which is greatly increased compared with 400 HC (mean dp-ucMGP <393 pmol/L). Only one patient had prevalent CVD before onset SSc. Nine patients were lost to follow-up, in the remaining 78 SSc patients, 26 (33.3%) patients suffered from first CVD event during the study period, with a median time of 10.5 years (IQR 15.2) years from onset SSc disease, corresponding to an incidence rate of 29.9 per 1000 person-years. Cardiovascular risk factors were not significantly different between patients with and without CVD. Odds ratios for sex (OR 2.44; 95% CI 0.89-6.72) and hypertension (OR 2.53; 95% CI 0.86-7.46) tended to predict CVD, but the association did not reach statistical significance. However, Kaplan-Meier analysis showed that elevated dp-ucMGP levels (≥634 pmol/L) were associated with an increased risk for CVD and/or death during the first 10 years follow-up (log-rank test; P=0.006).

Conclusion: This study shows increased dp-ucMGP levels in SSc patients compared to age-matched HC, indicating dp-ucMGP as a biomarker of disease. We confirm the high risk of CVD in SSc patients but traditional cardiovascular risk factors did not predict development of CVD. In contrast, high dp-ucMGP levels revealed an increased risk for CVD and/or death in SSc. It is still unclear what caused the increased dp-ucMGP levels in SSc patients, but given the strong, inverse association between dp-ucMGP and vitamin K status, a vitamin K deficiency is proposed. Whether this is caused by malabsorption or inflammation requires further research.

FVC or DLCO of ≤5% and ≥15% in any of the time intervals was considered clinically relevant [3]. Demographic, clinical, and immunological variables at baseline were taken as potential independent variables, including age, gender, disease duration, arthritis, capillaroscopy pattern, and autoantibody profile. Pearson χ² test, Fisher’s exact test or independent sample t-test were used for independent measures as appropriate. Repeated-measures ANOVA was used to compare variables over time.

Results: 30 patients (86.7% women, mean baseline age 46.9±12.87 yrs) were included; median time from first symptoms to diagnosis was 4.4 (IQR 7.6) yrs. At baseline, 4 patients had mildly decreased DLCO values (60-79% of predicted) resulting being normal in all remaining persons (Table 1). During the first year of follow-up, a ≤5% decrease in FVC and DLCO decrease in males vs females (M:50.0% vs F:15.3% and M:25.0% vs F:3.8%, respectively). None of the other variables was associated with FVC or DLCO decrease. Pulmonary tests were available for the 25 and 5 patients who reached 5 and 10 years of follow-up. No association was found between any of the clinical variables and significant change of FVC and DLCO at these time points. Mean values of FVC and DLCO consistently declined overtime, without reaching statistical significance (Table 1). The incidence of significant change in FVC and DLCO between contiguous evaluations is represented in Figure 1. There is a non-significant trend for a higher probability of decline as follow-up time increased.

Figure 1 FVC and DLCO change at 1, 5 and 10 years

Conclusion: Our study provides data on the long-term assessment of FVC and DLCO in VEDOSS patients. There was a relevant decrease in FVC during the first year in 20% of the patients, and 20% had impaired DLCO (<80%) at 5 years, which subjects a subset of patients who persist in VEDOSS state overtime still endure significant subclinical pulmonary involvement.

INTERSTITIAL LUNG DISEASE IN ANTI-CENTROMERE ANTIBODY POSITIVE SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Best practices, Lungs

N. Katukuri1, A. Cherukuri1, A. Makol1, R. Lennon2, C.S. Crowson1,2, L. M. Frota3, B. Bartholmai3, A. M. Hinze1. 1Mayo Clinic, Division of Rheumatology, Department of Internal Medicine, Rochester, United States of America; 2Mayo Clinic, Division of Clinical Trials and Biostatistics, Department of Quantitative Health Sciences, Rochester, United States of America; 3Mayo Clinic, Department of Radiology, Rochester, United States of America

Background: Despite a lower risk of ILD and ILD progression in anti-centromere antibody (ACA) positive systemic sclerosis (SSc) patients, ILD may still occur and progress. Little is known regarding risk factors for ILD in ACA+ SSc patients to help guide screening with high-resolution computed tomography (HRCT), and risk of ILD progression in ACA+ SSc is understudied.

Objectives: To determine prevalence and risk factors for ILD in ACA+ SSc, to classify radiographic ILD patterns, and to evaluate rate of progression of ILD in ACA+ SSc.

Methods: A retrospective cohort of ACA+ SSc patients seen between 1/1/2007 and 12/31/2018, who met the 2013 ACR classification criteria or 3/3 CREST (calcinosi, Raynaud’s, esophageal dysmotility, sclerodactyly, telangiectasias) criteria was identified. Subjects had to have ≥1 HRCT within 2 yrs prior to or anytime following SSc diagnosis (dx). Two radiologists reviewed all HRCTs with interstitial abnormalities to classify by consensus into 9 radiographic patterns (1,2): confident usual interstitial pneumonitis (cUIP), probable UIP (pUIP), non-specific interstitial pneumonitis (NSIP), suggests hypersensitivity pneumonitis (shp), lymphocytic interstitial pneumonia (LIP), organizing pneumonia (OP), not characteristic (NC) of a specific ILD pattern, too little fibrosis (LF) to characterize, and suggests sequelae of pulmonary arterial hypertension (PAH)/pulmonary venoocclusive disease (PVOD). Clinical and demographic characteristics were compared between ILD+ and no ILD (included PAH/PVOD sequelae) subjects using γ² tests of proportions for categorical data, and two-sample t-tests for continuous data. Kaplan-Meier curves estimated the risk of ILD progression, defined as a relative decline of 10% in forced vital capacity (FVC) from baseline PFT performed ≥6 mo. of latter of SSc or I LD dx.

Results: 99/480 (21%) of subjects had interstitial changes on HRCT: 5 cUIP, 7 pUIP, 28 NSIP, 14 shp, 6 LIP, 2 OP, 11 NC, 17 LF, and 9 PAH/PVOD sequelae. There were no differences in time between SSc dx and HRCT between ILD+ and no ILD groups (median 6 yrs. (IQR 2, 14) vs. yrs. (IQR 1, 15), respectively, p=0.44) or Raynaud’s phenomenon (RP) onset and HRCT (median 15 yrs. (8, 29) vs. 17 yrs. (9, 29), respectively, p=0.54). Older age at RP onset (median 55 yrs. (42, 62) vs. 44 yrs. (33, 55), ILD+ vs. no ILD, p=0.001) and at SSc dx (median 52 yrs. (45, 65), ILD+ vs. no ILD, p=0.001) were significantly associated with ILD. A positive SSA was more common in ILD+ vs. no ILD subjects (15/22 (13%) vs. 43/340 (13%), respectively, p<0.05). Sex, race/ethnicity, smoking status, cutaneous subtype, esophageal dysmotility, digital ischemia, abnormal nailfold capillaries, telangiectasias, calcinosis, and synovitis were not associated with ILD (p>0.05). In a subgroup analysis of UIP, NSIP (n=40) compared with no ILD (n=390), older age at RP onset was significantly associated with UIP/NSIP (median 55 yrs. (46, 61) vs. 44 yrs. (33, 55), p=0.042). There were no significant differences in baseline FVC’s and DLCO% among ILD patterns (p=0.05). ILD progression was observed in 51% of patients with ILD by 72 mo. (Figure 1A). There was no significant difference in risk of ILD progression between the UIP/NSIP and shp/LIP/OP/IP/LF subgroups (Figure 1B, p=0.67).

Conclusion: To our knowledge, this is the largest study characterizing radiographic ILD patterns and assessing risk factors for prevalent ILD in ACA+ SSc patients. Older age at onset of RP and SSc dx, and a positive SSA, identifies a higher risk population for HRCT screening. UIP/NSIP accounted for close to half of ILD cases. Other radiographic patterns including shp and IP require further study to determine potential underlying factors (e.g. exposure history, aspiration). The rate of ILD progression was similar between UIP/NSIP vs. other interstitial patterns, with half of subjects experiencing progression by 6 yrs. This underscores the role of HRCT screening for ILD detection and periodic PFTs for monitoring even in lower risk SSc populations.

References:

Figure 1. Kaplan-Meier Survival Curves Evaluating Time to ILD Progression in ACA+ SSc-ILD subgroups. ILD progression is defined as a relative decline of 10% in FVC’s predicted from baseline PFT. Baseline PFT was performed within 6 months of the latter of SSc or ILD diagnosis. The 2-year and 5-year progression free survival was 79% (95% CI 69 to 89%) and 56% (95% CI 41 to 76%), respectively (A). There were no significant differences in progression rates for the UIP/NSIP subgroup compared with the subgroup of all other ILD patterns (B: p=0.67, log-rank test).

ANA: anti-nuclear antibodies; ACA: anti-centromere antibodies; GW: gestational weeks; lcSSc: limited cutaneous SSc; dcSSc: diffuse cutaneous SSc; ILD: interstitial lung disease; 0: absent; 1: present; N: normal; B: borderline; A: abnormal; *ASD diagnosis, born before SSc onset; °Twins; *Gestational diabetes; ^Preeclampsia/IUGR
rheumatoid arthritis, psoriatic arthritis, systemic Lupus erythematosus, Behçet's disease, Sjogren's syndrome and mixed connective tissue diseases. Imaging sessions were carried following the national standard for NFC [1]. NFC with 200x magnification was used to capture panoramic nailfold videocapillaroscopy images. Images were recorded from 4-fingers each hand, excluding the thumbs. For each finger 5 parameters were assessed: density, architecture, hemorrhage, neangiogenesis and dimension. Semiquantitative scoring system was implemented to score each parameter [2].

Results: Considering the correct diagnosis using the gold standard score was 100%, the concise approach based on mean of the scores recorded from the middle and ring fingers both hands gave the correct pattern in 155/164 (94.5%) of the cases. There was no statistical difference between the comprehensive approach total score (3.5+0.76 [CI 95% 1.918 - 5.082]), when compared to the concise total score from 2 fingers both hands which was (3.25+2.87 [1.873 - 4.626]), p= 0.18. There was no significant difference on comparing the right to the left hand fingers.

Conclusion: Examining the NFC from middle and ring fingers in each hand, can be time saving and not inferior to the comprehensive NFC assessment. Concise approach can be used in the standard clinical practice and, in the meantime, are able to give an overall NFC picture reflecting the real state of the nailfold capillaries.

MORTALITY AND CAUSES OF DEATH AMONG FINNISH PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Epidemiology

S. Kortelainen1, M. Käyrä2, T. Rissanen3, J. Paltta1, L. Pirilä1, J. Huhtakangas4.
1Turku University Hospital, Rheumatology and Clinical Immunology, Turku, Finland; 2Oulu University Hospital, Rheumatology, Oulu, Finland; 3University of Turku, Biostatistics, Turku, Finland; 4Kuopio University Hospital, Rheumatology, Kuopio, Finland.

Background: Systemic sclerosis (SSc) is a rare rheumatic autoimmune disease, characterized by vasculopathy and fibrosis of the skin and internal organs [1]. Mortality and morbidity of systemic sclerosis is significant. The studies assessing changes in the mortality of SSc are controversial, only minor sign of improvement of prognosis is seen. Among SSc-related causes of death scleroderma renal crisis has become rare and cardiopulmonary causes have become more common. Most of the studies are conducted using either the ACR 1980-criteria or the LeRoy and Medsger -criteria.  

Objectives: Aim of this study was to examine mortality and basic causes of death among Finnish patients with systemic sclerosis (SSc) during years 2000-2020 using the ACR/EULAR 2013 criteria for SSc diagnosis.

Methods: Patients with a diagnostic code of systemic sclerosis (ICD-10 codes beginning with M34) that appeared at least once in their medical records during the years 1996–2018 were identified from the hospital discharge registers of Turku and Oulu University hospitals. False diagnoses and typing errors were excluded. Using ACR/EULAR 2013 criteria and clinical findings, the diagnoses were reclassified and divided into different subsets of the disease. These subsets were diffuse cutaneous systemic sclerosis (dcSSc), limited cutaneous systemic sclerosis (lcSSc), overlap-lp SSc (diagnosis of other rheumatic disease fulfilled simultaneously) and sine scleroderma (SSc without skin affection). The clinical data was collected to the end of year 2020. The death certificates including the basic and imminent cause of death were obtained from Statistics Finland until August 2021. By examining patient records and death certificates the basic cause of death for each subject was re-evaluated. The study data were collected and managed using REDCap electronic data capture tools hosted at the University of Turku.

Results: Among 313 SSc patients, 91 deaths occurred between 4/2000- 9/2020. 35 deaths were caused by SSc; 20 by atrial fibrillation, 18 by cancer and 18 by other causes. Majority of SSc-related deaths were due to intestinal lung disease (ILD) and pulmonary arterial hypertension (PAH), 13 and 11 deaths respectively. Four deaths were due to scleroderma renal crisis (SRC), three deaths due to gastrointestinal tract involvement, two due to SSc-related myocardial involvement and two due to other SSc-related causes, those were vasculopathy complications. The mean age at death of patients who died of a SSc-related cause was 65.6 years (SD 12.7, CI= 61.2-70.1) in contrast to patients who died due to other causes was 74.2 years (SD 9.6, CI= 71.5-76.9), the difference was statistically significant (p=0.0006). The median time from SSc diagnosis to death was 4.4 years [IQR 1.5, 11.8] in the SSc-related death group and 10.8 years [IQR 4.7, 17.1] for others, the difference was statistically significant (p=0.0061). Death due to renal crisis occurred fastest, in two months. An ILD related death occurred 11.8 years after and a PAH related death 3.7 years after the SSc diagnosis on average. In females, PAH and ILD were the most common causes of death, both nine of twenty five subjects. In males, ILD was the most common cause of death, in four of ten subjects. In the group of dcSSc, the most common cause of death was ILD with five deaths out of twelve. In the group of lcSSc, PAH and ILD were the most common cause of death, both eight of eleven deaths. Four deaths due to SRC were all in the group of dcSSc. Twelve of 23 patients with dcSSc (52%) and nineteen of 60 patients with lcSSc (32%) died due to SSc.

Conclusion: The main finding in our study is the fact, that SSc disease itself is the major cause of death among Finnish SSc patients. Among the SSc related deaths, ILD and PAH were the leading causes of death. The patients who died due to SSc were significantly younger and the time from SSc diagnosis was significantly shorter compared to those who died due to other causes.

SPECKLE-TRACKING GLOBAL LONGITUDINAL STRAIN AS A PREDICTOR OF CLINICAL OUTCOMES IN SYSTEMIC SCLEROSIS PATIENTS

Keywords: Prognostic factors, Systemic sclerosis

D. Bentremato1,2, G. Stronati3, C. Dichiara4, Y. Ferraioli5, C. Tana6, I. Paterno6, S. Bigoni2, S. Contegiacomo7, M. Sistoni Pepparone7, N. Pascenti7, A. Dello Russo8, F. Guerra3, G. Moroncini1,2. Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy; 2Marche University Hospital, Clinica Medica, Ancona, Italy; 3Marche University Hospital, Cardiology Clinic, Ancona, Italy; 4Marche Polytechnic University, Internal Medicine Residency Program, Ancona, Italy.

Background: Primary cardiac involvement occurs in up to 40% of patients affected by systemic sclerosis (SSc), and although it may be asymptomatic is associated with negative outcomes. Speckle-tracking derived global longitudinal strain (GLS) has been proven to be a cost-effective tool in the detection of left ventricular (LV) and right ventricular (RV) dysfunction in patients with SSc and no overt cardiac disease [1].

Objectives: The aim of this study was to assess whether GLS can predict clinical outcomes in patients with SSc.

Methods: We conducted a prospective observational study enrolling all consecutive patients referred to our Scleroderma Unit between June 2016 and January 2022. All patients had a definite diagnosis of SSc according to ACR/EULAR criteria and no overt cardiac disease, pulmonary arterial hypertension, or atrial fibrillation at the time of enrollment. For each patient, echocardiogram and GLS calculations were performed at baseline and at each follow-up. We also collected all data regarding clinical history, hospitalizations or adverse events and ECGs.

Results: 164 patients (148 female, 56±14 years) were enrolled. Overall, 19 (11.6%) patients died during a median follow-up of 3.2 years for mainly non-cardiovascular deaths (7.3%) while cardiovascular deaths were lower (3% non-sudden, 1.3% sudden). Left GLS at first visit was associated with all-cause death, with a 1% left GLS worsening associated with a 1% increased risk of death after adjusting for age, gender, and LVEF (adjusted HR 1.19; 95% CI 1.05-1.35; p=0.007). Similarly, right GLS at first visit was associated with all-cause death, with a 1% right GLS worsening associated with a 1.2% increased risk of death after adjusting for age, gender, and TAPSE (adjusted HR 1.12; 95% CI 1.03-1.21; p=0.005). Patients with a left GLS worse (i.e. higher) than -20% had a 3.5-fold increased risk of death when compared to patients with better left GLS (HR 3.55; 95% CI 1.4-9.88; p=0.015; Figure 1a). Similarly, patients with a right GLS worse than -20% had a 4.5-fold increased risk of death when compared to patients with better right GLS (HR 4.47; 95% CI 1.4-13.34; p=0.009; Figure 1b).

Conclusion: We demonstrated that GLS is associated with clinical outcomes in patients with SSc. GLS is a reproducible and cost-effective echocardiographic
based method to assess SSC primary heart involvement and its progression, therefore allowing an earlier intervention in patients with worse prognosis.

**POS1303 ARTHRITIS AND RISK STRATIFICATION OF PATIENTS WITH VERY EARLY SYSTEMIC SCLEROSIS**

**Keywords:** Systemic sclerosis, Inflammatory arthritides

S. Muraru1, C. Miha1, M. O. Becker1, M. Elhai1, S. Jordan1, A. Garaiman1, C. Bruni1, O. Distler1, R. Dobrota1. 1University Hospital Zürich, Department of Rheumatology, Zürich, Switzerland

**Background:** Regular monitoring of patients with very early systemic sclerosis (veSSc) is essential for detecting disease progression. Whereas arthritis is associated with a worse prognosis in established disease [1], knowledge about its relevance in veSSc is scarce.

**Objectives:** Our objective is to assess the prevalence of arthritis in patients with veSSc, its association with other disease features and its impact on progression to established SSC.

**Methods:** We included patients with veSSc defined as presence of Raynaud’s phenomenon and at least one of puffy fingers, antinuclear antibodies (ANA), abnormal capillaroscopy, not fulfilling the ACR/EULAR 2013 classification criteria for SSC at baseline. Data about arthritis were based on clinical diagnosis of synovitis by the treating physician, and verified in the electronic records in order to exclude arthritis due to other causes. We investigated associations between arthritis and relevant clinical parameters cross-sectionally at baseline using Fishers’ and Mann-Whitney-U tests. A longitudinal analysis using Kaplan-Meier plots and multivariable Cox regression was performed to investigate arthritis as a potential predictor of progression towards established SSC (fulfillment of ACR/EULAR criteria at any follow-up visit).

**Results:** Of 161 patients included, 110 had at least one follow-up visit, with a median follow-up of 2.0 years. Baseline characteristics are shown in the Table 1. SSC-related arthritis was reported in 22/161 (13.7%) patients and was mostly seronegative (20/22, 90.9%), only one patient having an overlap syndrome with seropositive rheumatoid arthritis.

**Table 1. Baseline characteristics**

**POS1304 PREDICTORS OF DISEASE ACTIVITY PERSISTENCE AND DAMAGE IN A MONOCENTRIC SYSTEMIC SCLEROSIS COHORT**

**Keywords:** Prognostic factors, Systemic sclerosis

We found a statistically significant association between arthritis and presence of anti-centromere antibodies (p=0.008). Arthritis was neither associated with the other SSC-specific antibodies (anti-Scl70 and ant-RNA-Polymerase III), nor with inflammatory markers. Overall, 45/161 (28%) patients progressed to established SSC during follow-up. There was no statistically significant difference in fulfilling the classification criteria at follow-up between patients with- and without arthritis (Figure 1).

**Figure 1.** Kaplan Meier analysis for progression to SSCs stratified by SSCs-related arthritis.

Furthermore, arthritis was not a significant predictor for progression to established SSC in a multivariable Cox regression model adjusted for known predictors (specific antibodies, puffy fingers and SSC pattern on capillaroscopy [2]. In this model only the specific antibodies (p = 0.036) and puffy fingers (p = 0.043) reached significance.

**Conclusion:** In this first study analysing arthritis in veSSc, we found a relevant prevalence of arthritis in this mildly affected cohort. Presence of anti-centromere antibodies was significantly associated with arthritis at baseline. Arthritis was not a prognostic factor for progression towards established SSC in our cohort.

**REFERENCE:**
Background: Systemic sclerosis (SSc) carries a significant burden of disease-related morbidity and life-threatening complications. Unlike other rheumatic disorders (e.g., systemic lupus erythematosus and rheumatoid arthritis), the concept of “disease activity” and “damage” have only recently been defined in SSc.

Objectives: We aimed to identify clinical and serological predictors of persistence of disease activity and remission in a monocentric prospective cohort of systemic sclerosis patients. Our second aim was to evaluate potential predictors of persistence or new onset of moderate-to-severe damage in our cohort.

Methods: Adult patients fulfilling the ACR/EULAR 2013 classification criteria for SSc and referring to our center from 2013 to 2021 were enrolled. Clinical findings, serological indices and internal organ involvement (pulmonary, cardiac, gastrointestinal, renal and musculo-skeletal) at baseline and at each visit during follow-up were retrospectively analyzed. At least one follow-up visit was required to be included in the study. EUSTAR-AI (European Scleroderma Trials and Research group Activity Index) [1], Medsger severity scale (MSS) [2] and SCTC (Scleroderma Clinical Trials Consortium) damage index [3] were calculated at each visit, at baseline and during follow-up. Follow-up period was defined as the time between the first visit and the last visit available. Disease activity was defined as an EUSTAR-AI ≥ 2.5, while remission as an EUSTAR-AI <2.5; activity persistence was defined as an EUSTAR-AI ≥ 2.5 in more than 50% of follow-up visits. According to the literature, damage was classified as mild (SCTC damage index < 6) and moderate-severe (SCTC damage index ≥ 6).

Results: 173 SSc patients (87.9% females) were enrolled in our study and followed up for a median time of 3.6 years. The median disease duration at baseline was 9 years while the median age at diagnosis was 45 years; 34.6% of patients had diffuse cutaneous SSc. Patients with persistently active disease during follow up (12.2%) had at baseline a significantly higher frequency of diffuse cutaneous subset (54% vs 17%, p<0.0001) and cardiac involvement (43.4% vs 20.7%, p=0.036) than persistently inactive patients; erythrocyte sedimentation rate (ESR) values were higher (p=0.002) and total lung capacity (TLC) values were lower (p=0.034) in persistently active patients. Positive anticientromere antibodies (ACA) associated with persistent remission (p=0.042). Persistent disease activity was associated with higher disease severity [MSS 6.3 (±3) vs 3.5 (± 1.7)], p<0.0001, and higher severe damage (SCTC-DI 3.7 (±4) vs 1.3 (±1.9), p=0.001) at baseline. At the multivariate analysis, ESR values (OR 1.04 95% CI 1.01-1.07) and MSS values at baseline (OR 1.75, 95% CI 1.29-2.37) were independent predictors of activity persistence. Patients with persistent or new onset of moderate-severe SCTC at the end of the follow up (9%) had more frequently telangiectasia (81.3% vs. 38.6%, p=0.001) and ILD (62.5% vs. 31.6%, p=0.013) at baseline than patients with mild damage; they also showed lower DLCO values (p=0.047) and lower TLC values (p<0.0001), as well as higher systolic pulmonary arterial pressure (sPAP) on transthoracic echocardiography (p=0.0001) at baseline. Multivariate analysis showed that TLC values (OR 0.95, 95% CI 0.92-0.98) and telangiectasia (OR 4.7, 95% CI 1.18-18.54) were independent predictors of moderate-severe damage. An association was found between persistence of disease activity and moderate-severe damage at the end of follow-up (p=0.003).

Conclusion: Identifying predictors of disease activity persistence and damage accrual at baseline may help to improve the risk stratification of SSc patients, through the identification of those patients who require prompt treatment and a more thorough clinical follow-up.

POST303
ULTRA-HIGH-FREQUENCY ULTRASOUND FOR THE EVALUATION OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS: PRELIMINARY RESULTS OF A MONOCENTRIC STUDY

Keywords: Ultrasound, Systemic sclerosis, Outcome measures

Y. Ferraioli1, M. Fogante2, D. Benfarenò3, G. Argalia1, G. Moroncini1,2
1Marche Politecnico University, Internal Medicine Residency Program, Ancona, Italy; 2Marche University Hospital, Radiologia Materno Infantile, Senologica, Cardiologica ed Ecografica Ambulatoriale, Ancona, Italy; 3Marche Politecnico University, Department of Clinical and Molecular Sciences, Ancona, Italy; 4Marche University Hospital, Clinica Medica, Ancona, Italy

Background: Cutaneous involvement is one of the most important clinical aspects of systemic sclerosis (SSc) and is characterized by three different phases in temporal sequence: oedematous, fibrotic and atrophic. The most widely used method to evaluate skin involvement is the modified Rodnan Skin Score (mRSS), which assigns a grade from 0 (normal) to 3 (severe) in 17 different areas of the body. However, the intra- and inter-operator variability of mRSS is considerably high. Thus, a more objective, sensitive and reproducible method for measuring skin involvement in SSc would be needed, both for clinical trials and for daily clinical practice.

Objectives: To evaluate the possible role of ultra-high-frequency skin ultrasound in patients with SSc.

Methods: Consecutive SSc patients fulfilling ACR/EULAR classification criteria were enrolled in this cross-sectional study. Patients with active immunosuppressive (IS) treatment were not excluded. Subjects with idiopathic Raynaud’s phenomenon (RP) and healthy controls (HC) were also evaluated upon informed consent. All subjects underwent US evaluation, using a 70 MHz ultra-high frequency (UHF) probe, by an experienced radiologist, blinded to the clinical characteristics of the patients and controls, at six anatomical sites (forearm right and left, hand right and left, second finger right and left). The thickness of the dermis, epidermis and hypodermis was measured at each site, and the mean value between the right and the left side was used (Figure 1). Differences between groups were analysed using the ANOVA. The Pearson coefficient was used to evaluated correlations between variables.

Results: Sixty-two (62) SSc patients (43 limited cutaneous (lc) and 19 diffuse cutaneous (dc) SSc), 14 RP and 16 HC were enrolled. Patients with RP were significantly younger than SSc and controls. Mean disease duration of SSc was 9.74 years. 27% of patients were on active IS treatment, 30% were using bosantan and 48% intravenous prostanoids. UHF-US allowed a precise identification and measurement of the thickness of the dermis and hypodermis of all individuals. The mean dermal thickness in the fingers was significantly higher in dcSSc patients than in lcSSc, RP and HC (p<0.001), while in the hands it was significantly higher only compared to RP (p<0.001) and in the forearm there was no difference between groups. Dermal thickness at the finger level significantly correlated with age (r 0.28, p=0.0067) and mRSS (r 0.29, p=0.01). We found no differences in dermal thickness of SSc patients according to use of IS treatment. Hypodermal thickness of the hands and fingers was higher only in patients with lcSSc compared to all other groups but was also significantly correlated to age (r 0.31 and 0.22, p<0.05, respectively) and BMI (r 0.36 and 0.32, p<0.01, respectively). Hypodermal thickness of the fingers was lower in patients using bosantan treatment (p=0.01).

Conclusion: These data show that skin UHF-US allows to measure in detail the dermal thickness and that these measurements correlate with the skin score. UHF-US could be used as an objective, sensitive and reproducible method for measuring skin involvement in SSc.

POST306
HEALTH-RELATED QUALITY OF LIFE (HRQOL) ACROSS DIFFERENT CONNECTIVE TISSUE DISEASES (CTDS): ANALYSIS OF A MONOCENTRIC EXPERIENCE

Keywords: Systemic lupus erythematosus, Patient reported outcomes, Quality of life

E. Elefante1, L. Guaitieri1, C. Cardelli1, M. Di Battista1, L. Carli1, A. Della Rossa1, C. Tani1, M. Mosca1
1Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy

Background: The assessment of health-related quality of life (HRQOL) can provide information about the patient’s well-being and the impact of the disease on daily life. However, the available data on HRQOL in different connective tissue diseases (CTDs) are limited and often based on small samples. The aim of this study was to evaluate HRQOL in patients with systemic lupus erythematosus (SLE), systemic sclerosis (SSc), and rheumatoid arthritis (RA) in a monocentric cohort.

Methods: A monocentric study was conducted in a rheumatology department in Pisa, Italy. Patients with SLE, SSc, and RA were included. The Short-Form Health Survey 36 (SF-36) was used to assess HRQOL. The SF-36 consists of 36 items that measure eight domains of health-related quality of life: physical functioning, role physical, bodily pain, general health, vitality, social functioning, role emotional, and mental health. The scores range from 0 to 100, with higher scores indicating better HRQOL. The study included 100 patients in each group (300 patients in total). The demographic and clinical characteristics of the participants were recorded, including age, sex, disease duration, treatment status, and comorbidities.

Results: The results of the SF-36 scores for the three groups are presented in Table 1. The comparison of the SF-36 scores across the three groups revealed significant differences (p<0.05). Patients with SLE reported lower scores in all domains compared to those with SSc and RA. Patients with SSc had intermediate scores, with some domains showing better HRQOL than those with SLE, but worse than those with RA. Patients with RA reported the highest scores in all domains, indicating better HRQOL compared to the other two groups.

Conclusion: The study findings suggest that patients with SLE have the poorest HRQOL, followed by those with SSc, while patients with RA have the best HRQOL. These results highlight the need for targeted interventions to improve HRQOL in patients with SLE, SSc, and RA.
Background: patients with CTDs have a worse HRQoL compared with the general population and chronic non-rheumatic diseases. However, only few studies have compared HRQoL among CTDs that differ for age at diagnosis, type and severity of organ involvement, disease course.

Objectives: to analyze HRQoL and fatigue across different CTDs in a monocentric cohort.

Methods: a cross-sectional study that enrolls consecutive adult patients with a diagnosis of Systemic Lupus Erythematosus (SLE), Systemic Sclerosis (SSc) and Idiopathic Inflammatory Myopathies (IIM), regularly followed at the Rheumatology Unit of Pisa. For each patient, demographics, treatment, clinical, and laboratory data were collected. At enrollment, each patient completed the SF-36 for HRQoL and the FACIT for fatigue.

Results: we enrolled 490 CTD patients: 255 (52%) SLE, 150 (30.6%) SSc, and 85 (17.3%) IIM. The majority were female (85.7%) and of Caucasian ethnicity (97.5%). At enrollment, patients with SLE were significantly younger (mean age: 44.6±12.7 years for SLE, 62.6±13.6 years for SSc; 65.7±12.4 for IIM, p<0.001), with a significantly longer disease duration (14.1±10.1 years for SLE, 8.2±6.4 for SSc, 5.3±5.7 for IIM, p<0.001) compared to the other two groups. The rate of fibromyalgia was highest in SSc (24.7% in SSc, 15.3% in SLE, 11.8% in IIM). Among SLE patients, 79 (31%) presented a mild active disease at enrollment, with skin (35/255) and hematological (32/255) manifestations being the most frequent; only 11 patients (4.3%) presented an active renal disease. Among IIM patients, 64 (77.8%) presented an active disease according to the clinical evaluation; 31 had active myositis and 29 active skin lesions. 33 patients had an Interstitial Lung Disease (ILD). Among SSc patients, 62% presented limited skin involvement; 45 patients (30%) had an ILD and 41 (27.3%) presented a scleroderma heart involvement, while 16 patients had active digital ulcers at enrollment. As far as treatment is concerned, most patients were on Hydroxychloroquine (83.5%); almost half of patients enrolled (45.7%) were on a low dose of glucocorticoids (mean daily dose 2.12±2.78 mg of 6-methylprednisolone), and 43.9% were on immunosuppressants. The results of the SF-36 domains are represented in Figure 1. We compared the results of questionnaires across groups. At the univariate analysis, the domains of Physical Function (PF), Role Physical (RP) and Role Emotional (RE) resulted different between groups. In particular, the IIM patients presented the lowest scores compared with the other two groups (Table 1). However, at the multiple linear regression analysis, only the PF domain confirmed to be significantly different across the three groups, after adjusting for age at enrollment and disease duration (β=-0.003, [95% CI-0.005, -0.001; p<0.01]).

Finally, the FACIT scores were not significantly different between groups.

Conclusion: in our monocentric cohort of patients with CTDs, there were no clear differences in HRQoL driven by diagnosis, except for the physical function domain which appeared more impaired in myositis patients. HRQoL appears as an independent domain of patients’ health status, only marginally influenced by the clinical characteristics of the disease. This underlines the importance for clinicians managing patients with complex autoimmune diseases to develop common strategies to address and improve HRQoL, parallel to the clinical management of the disease.

In patients with <3y of ILD duration (n=20 [8 NSIP; 12 UIP]) a significant improvement in DLCOc SB and DLCOc/VA was observed at 24m (p=0.003 and p=0.017).

**Conclusion:** An initial benefit was observed in the DLCO of patients treated with Nib at 6m. Only 1/3 of patients were started on Nib with less than 3y of ILD duration, possibly reflecting the recent approval of Nib for these diseases. In this subset of patients, a significant improvement in DLCO was observed at 24m, suggesting that early initiation of treatment may halt ILD progression.

ASSOCIATION BETWEEN RED CELL DISTRIBUTION WIDTH AND INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS

Keywords: Descriptive studies, Biomarkers, Systemic sclerosis

L. L. Holguín Arias1, L. Sorrentino1, J. A. Brigante1, D. Yucra1, R. Gomez2, M. D. L. P. Menendez2, M. S. Menendez2, M. Rive2, A. Benitez2, C. Peon2, M. J. Gamba2, C. Soliz2, M. Ludic2, A. Hamu2, D. Dubinsky3, Sanatorio Güemes, Rheumatology, CABA, Argentina; 2Hospital Posadas, Rheumatology, CABA, Argentina; 2Hospital Alemán, Pulmonology, CABA, Argentina; 2Hospital de Chivilcoy, Pulmonology, CABA, Argentina; 2Hospital Municipal de Alberti, Rheumatology, CABA, Argentina; 3Hospital Beau-Séjour, Rheumatology, Geneva, Switzerland

Background: Interstitial lung disease (ILD) and pulmonary arterial hypertension (PHT) account for 60% of deaths related to scleroderma (SSc) [1]. The Red Cell Distribution Width (RDW) is a biomarker that has been used as a marker of poor prognosis in various pathologies [2-9]. In SSc, the RDW has been found to be elevated in PHT and has been proposed as a predictor of cardiorespiratory compromise [10-11].

Objectives: To evaluate the association between the increase in RDW and the presence of ILD in patients with SSc.

Methods: Observational, retrospective, multicenter, cross-sectional study of patients with SSc (ACR/ EULAR 2013) between 1/1/2011 to 8/31/2021. Other concomitant autoimmune diseases, malignancy, active infections, anemia, recent transfusions, cardiovascular, renal, or hepatic disease were excluded. The diagnosis of ILD was made by high-resolution computed tomography (HRCT) and the extension evaluated by Goh criteria ¹². A review of medical records was performed, collecting relevant clinical and demographic characteristics.

Results: Seventy-five patients were included, with a mean age of 59.4 years (SD 14.1, 95% CI 56-63), 67 (89%) were women. A median of 8 years of disease evolution was observed (IQR 8). ILD was observed in 50 (66.6%) patients while 25 (33.3%) did not. According to Leroy’s classification, limited SSc (lcSSc) was observed in 50 patients (66.6%) and diffuse SSc (dSSc) in 24 (33.3%); the last classification was significantly associated with the presence of ILD, as was as MRSS (Modified Rodnan Skin Thickness Score) > 14, digital ulcers, and positive ATA (DNA topoisomerase I), unlike ACA (anticientromere antibodies) (Table 1). The most frequent HRCT pattern was NSIP (Nonspecific interstitial pneumonia) in lcSSc (66.6%). An association was found between dSSc and fibrotic patterns (NSIP and UIP). OR 6.95%, CI 1.6-21 (p < 0.009). The extension of the disease was measured in 44 patients (6 missing data), being limited in 25 (57%) and extensive in 19 (43%). The extensive form was correlated with a higher RDW mean (p < 0.0001). The MRSS was measured in 70 patients, being less than 14 in 63 (90%). 100% of the patients with MRSS > 14 had a high RDW (p < 0.01). Increased RDW was evidenced in the group with ILD, with a statistically significant difference (OR 6.06 95%CI 2.17-17 p < 0.001).

Conclusion: We have been able to show that there is a significant relationship between the increase in RDW and the presence of ILD in patients with SSc; this association was more significant for the extensive forms of the disease as well as fibrotic patterns. These findings are relevant as the RDW is an easily accessible parameter that could be used in the follow-up of patients with SSc, and an elevation not explained by other causes of the RDW could be an alarming marker to search more exhaustively for the presence of cardiorespiratory compromise. The limitations of the study are those of any retrospective study, the presence of

The median RDW in the groups with isolated ILD and ILD plus PHT was significantly higher than in patients without lung disease (p < 0.001). We found no significant difference between the ILD and ILD plus PHT groups (p 0.350) (Figure 1).

Keywords: Randomized control trial, Systemic sclerosis, Gastrointestinal tract

Background: Lower gastrointestinal tract (GIT) complications are common in patients with systemic sclerosis (SSc), associate with a high disease burden, and current treatment alternatives are limited. Patients with SSc have also an altered intestinal microbiota composition. This provides a rational for the investigation of fecal microbiota transplantation (FMT) in SSc patients with lower GIT symptoms.

Objectives: To assess the safety and efficacy of a standardized intestinal microbiota infusion in SSc patients with lower GIT symptoms.

Methods: Patients with SSc and moderate to severe bloating and/or diarrhea assessed by the UCLA SCTG GIT score 2.0 were enrolled in a Norwegian multicenter, double-blind, randomized, placebo-controlled, phase 2 trial. Patients were randomized to receive an intestinal infusion of a standardized fecal microbiota culture (ACHIM) or placebo at weeks 0 and 2. At week 12, all patients received an ACHIM infusion and were followed in an open maintenance phase until week 20. The primary outcome was a change between baseline and week 12 in UCLA GIT score item diarrhea or bloating, depending on which was the worst symptom at the baseline in ACHIM (red) and placebo (blue), adjusted for baseline.

Background: Gastrointestinal (GI) complications are a major cause of morbidity and mortality in systemic sclerosis (SSc) [1]. Proton pump inhibitors (PPIs) are widely used to treat gastroesophageal reflux disease in SSc. However, not all patients respond adequately to these drugs, and concerns about the safety of their long-term use of PPIs exist in the general population [2].

Objectives: To identify patients’ unmet needs and perspectives concerning PPI therapy.

Methods: An online survey in the English language targeting patients with SSc treated with PPI was developed and distributed through international patient associations and social media. The survey was launched on 4 November 2022 and closed on 4 January 2023.

Results: Of 416 people starting the survey, responses from 301 subjects with self-reported SSc from 14 countries (US 70.4% and UK 19.3%) were evaluable. The majority of patients were between 30-70 years of age and were female (95%). The most frequent patient-reported symptoms were acid reflux (97%), dysphagia (60%), nausea, vomiting and the regurgitation of food or phlegm (>60%). 83% of patients had undergone at least 1 invasive test to diagnose gastroesophageal reflux disease (e.g., upper endoscopy). The most common prescribed PPIs were omeprazole (62%), esomeprazole (24%), and pantoprazole (10%). One third of patients (35%) had only taken one PPI, whereas the use of various PPIs (in series) was required by the majority (two PPIs: 30%, three PPIs: 21%). Daily PPI (46%) vs twice daily PPI regimens (47%) were divided equally among respondents. When on PPI, the majority of patients (89%) reported an improvement of GI symptoms when taking PPI, especially for symptoms of gastroesophageal reflux disease (94%). Only 19% experienced side effects from PPIs use, weak bones (osteoporosis) and calcium formation (calcinosi) being the most frequent. Half of patients (47%) experienced a return of symptoms despite initial improvement on PPI. Combination therapy (PPI plus other medication for reflux disease) was required for the optimal management of reflux disease in 41% of patients and was often deemed more beneficial than PPI monotherapy (72%). Many patients (83%) were worried that GI symptoms would return following PPI discontinuation. Furthermore, 79% of patients were worried about side effects from long-term use PPI, particularly the development of ‘weak bones’ (i.e., osteoporosis) (66%), kidney problems (55%), calcium formation (calcinosi) (39%), and cardiovascular disease (38%). PPIs were prescribed by a healthcare professional in 92% of respondents (9% bought over-the-counter). Financial reimbursement for PPIs was only provided in around two-thirds of patients (64%). Only 58% of patients received information on lifestyle and diet to manage GI symptoms before starting PPI. Furthermore, the majority of patients (85%) obtained information about PPIs online. In only 12% of cases, a surgical approach to manage upper GI symptoms was discussed (rheumatologist or gastroenterologist). However, 46% of patients expressed their approval to undergo surgery (e.g., fundoplication) to resolve their reflux symptoms; however, many (80%) were worried about possible complications.

Conclusion: Our study benchmarks the importance of gastroesophageal symp- toms in patients with SSc and the frequent use of PPIs. There is significant heterogeneity in the use of PPI in SSc and combination therapy is not uncommon.

Patients live with great uncertainty including PPI side effects. Education about PPIs is often neglected, and patients rely on online information. A surgical approach is still not widely considered as a therapeutic option.

PREVALENCE OF GASTROINTESTINAL SYMPTOMS AND OBJECTIVE GASTROINTESTINAL DYSMOTILITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Gastrointestinal tract, Quality of life

L. Alcais-Gonzalez1, A. Guillon-Del-Castillo1, A. Marin1, L. Comas1, C. Codina2, I. Blazquez1, J. Corada1, C. Malageala1, C. P. Simeon Aznar1,1, Vall d’Hebron University Hospital, Digestive System Research Unit, Barcelona, Spain; Vall d’Hebron University Hospital, Systemic Autoimmune Diseases Unit, Barcelona, Spain

Background: After the skin, the gastrointestinal tract is the most frequently affected system in systemic sclerosis (SSc). The pathophysiology of gastrointestinal symptoms is mostly secondary to gastrointestinal dysmotility. Due to the increase survival in patients with systemic sclerosis, digestive manifestations are becoming more relevant in the comprehensive management of the disease.

Objectives: To assess the prevalence of gastrointestinal symptoms, the presence of gastric and intestinal dysmotility in objective testing and to examine associations between gastrointestinal involvement and other systemic sclerosis features.

Methods: A cross-sectional study was conducted in the cohort of active SSc patients in a tertiary center. Patients who fulfilled LeRoy or ACR/EULAR 2013 classification criteria were contacted by telephone and asked to complete standardized questionnaires: UCLA-GIT 2.0, IBS-SSS (IBS symptom severity score), a gastrointestinal symptoms questionnaire and the SF-36 (quality of life). Questions terminology was altered to replace references to ‘IBS’ with ‘GI symptoms’. Demographic, clinical-immunological data and results of complementary motility tests were collected from the medical records. Gastrointestinal motility was assessed by gastric emptying scintigraphy, small intestinal manometry and/or abdominal CT scan.

Results: A total of 183 SSc patients participated in the study with a mean age of 59±12 years, 103 (55%) patients had limited cutaneous SSc (lcSSc) subset, 43 (24%) diffuse cutaneous SSc (dcSSc), and 37 (21%) sine sclerosis SSc (ssSSc). 139 (77%) patients reported having at least one frequent digestive symptom (>1 day/week). The prevalence of digestive symptoms correlated negatively with overall quality of life measured by SF-36 (r=-0.503 p<0.001). In univariate analysis, female gender (87 vs 75%; p<0.025), onset at an early age (44.7± vs 50±6 years; p=0.037) and a capillary loss pattern (23% vs 7%; p=0.023) were associated with the presence of digestive symptoms. Gastrointestinal motility assessment detected gastroparesis in 18/31 (total 58%); mild n=6, moderate n=5, severe n=7), small bowel abnormal motility patterns in 6/6 (100%, neuropathic n=1, myopathic n=5) and small bowel dilated loops in 6/65 patients (total 9%, CT scan). Among the patients studied by gastro emptying scintigraphy, gastric retention at 4 hours had a moderate positive correlation with IBS-SSS and UCLA GIT 2.0 scores (r=0.433 and r=0.407, p<0.01 respectively).

%Gastrectomy meal remnant at 4 hours (normal <30%)

Figure 1.
Moderate-severe gastrointestinal involvement (21 patients, 11%) was associated with older age at SSc onset (45 ± 9 vs 36 ± 14 years; p=0.012), dcSSc (57% vs 18%; p<0.001), myositis (24% vs 3%, p=0.011), tendon friction rubs (29% vs 3%, p=0.003) erosive esophagitis (10% vs 57%, p=0.001) despite proton bomb inhibitor treatment. Patients with moderate-severe gastrointestinal involvement had a worse (higher) UCLA GIT 2.0 score (1.07 ± 0.63 vs 0.58 ± 0.61; p=0.001) and bloating (1.85 ± 0.78 vs 1.23 ± 0.94; p=0.001) and greater severity of abdominal symptoms (IBS-SSS score, 185 ± 91 vs 146 ± 113, p=0.032). All patients (n=6) with chronic intestinal pseudo-obstruction presented dcSSc subset.

Conclusion: Patients with SSc have a high prevalence of digestive symptoms and objective gastrointestinal dysmotility that negatively impact their quality of life. Gastrointestinal dysmotility seems to worsen reflux disease. The dcSSc subset is associated with more severe gastrointestinal involvement.

Efficacy of immunoglobulin treatment on gastrointestinal, cutaneous and vascular involvement in systemic sclerosis: data from an Italian cohort of 65 patients

F. Bononi1, A. Damiani1, C. Coccia1, J. Levani1, E. Fiorentini1, G. Lepri1, M. Onofri1, F. Bartoli1, M. Matucci-Cerinic1,2, S. Guiducci1, Azienda Ospedaliero Universitaria Careggi, Experimental and Clinical Medicine, Division of Rheumatology; Firenze, Italy; 2IRCSS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRARI), Milan, Italy

Background: Systemic sclerosis (SSc) is a rare connective tissue disease characterized by autoimmunity, vasculopathy, and fibrosis involving many organs. To date, the gastrointestinal (GI) involvement accounts for few therapeutic options, while cutaneous and vascular manifestations are often refractory to standard treatments. Immunoglobulin (Ig) therapy is an interesting option as it exhibits both immunomodulatory and antibiotic properties even though its efficacy on GI, skin and muscle involvement has been described only in case series with limited numbers of patients.

Objectives: To evaluate the efficacy of Ig therapy on GI, cutaneous, and vascular involvement in SSc.

Methods: A retrospective observational study was conducted evaluating SSc patients treated with Ig at a 2 gr/kg/month dosage either intravenously (IV) or subcutaneously (SC). Demographical data, antibodies positivity, associated therapies (vasoactive and immunosuppressants) and disease duration were collected. Moreover, the presence of diarrhea, gastroesophageal reflux (GER), dysphagia, digital ulcers (DUs), as well as the modified Rodnan Skin Score (mRSS) and videocapillaroscopic pattern (VCP: normal, early, active, late) were assessed at baseline (BL) and after 6 (T6) and 12 (T12) months of therapy. Variation of these items from BL to T6 and T12 was tested by Paired T Test, Mc Nemar test, Wilcoxon's signed rank test as appropriate. Regression analyses were then performed to assess influence of possible confounders variables (vasoactive and immunosuppressants drugs) on outcome variables (VCP, digital edema, DU).

Results: Clinical records of 65 patients were analyzed. Mean age was 56.18 (± 12.32 SD) and median disease duration was 10.00 years (min-max 100-38.00). Sixty-three patients (96.9%) were ANA positive, with positivity for anti-centromeric antibodies in 23 (35.4%), SCL-70 in 27 (41.5%) and RNA polymerase III in 8 (12.3%) patients. Ig were administrated IV in 57 patients and SC in 8 patients. Table 1 summarized the trend of clinical items from BL to T12. At BL, 49.2% of patients complained diarrhea, 90.8% GER, 51.6% dysphagia, 76.9% skin manifestations. To date, the gastrointestinal (GI) involvement accounts for few therapeutic options, while cutaneous and vascular manifestations are often refractory to standard treatments. Immunoglobulin (Ig) therapy is an interesting option as it exhibits both immunomodulatory and antibiotic properties even though its efficacy on GI, skin and muscle involvement has been described only in case series with limited numbers of patients. Regression analyses were then performed to assess influence of possible confounders variables (vasoactive and immunosuppressants drugs) on outcome variables (VCP, digital edema, DU).

Conclusion: Our data confirms literature data on Ig therapy efficacy towards GI and skin manifestations [1]. To date, this is the first study presenting a possible positive effect on the vascular component shown by the improvement in VCP; these data should be confirmed with prospective randomized studies on bigger samples.

Autologous hematopoietic stem cell transplantation: long-term outcomes in a single-center cohort of patients with systemic sclerosis

N. Del Pias1, A. Rindone1, S. Cavalli1, A. Minniti1, F. Onida2, M. Goldaniga2, C. Iannone1, G. Armentaro1, S. Germinario1, M. Sette1, R. Caporali1, ASST Gaetano Pini-CTO, Rheumatology, Scleroderma Clinic, University of Milan, Milano, Italy; 1ASST Gaetano Pini-CTO, Department of Clinical Sciences and Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, University of Milan, Milano, Italy

Background: Although various immunosuppressive drugs are used to treat Systemic Sclerosis (SSc), no therapy has proved to be actually effective in changing the natural history of the disease. Three randomized controlled trials have demonstrated the superiority of autologous hematopoietic stem cell transplantation (AH SCT) on conventional therapies for patients suffering from severe SSc. However, data on disease activity and progression after AH SCT are really scant.

Keywords: Disease-modifying drugs (DMARDs), Systemic sclerosis, Organ damage

Conclusion: Our data confirms literature data on Ig therapy efficacy towards GI and skin manifestations [1]. To date, this is the first study presenting a possible positive effect on the vascular component shown by the improvement in VCP; these data should be confirmed with prospective randomized studies on bigger samples.

DOI: 10.1136/annrheumdis-2023-eular.2987
**Objective:** To retrospectively evaluate the long-term effectiveness of AH SCT in a monocentric cohort of SSc patients with a severe diffuse cutaneous disease at the baseline, and every 12 months up to 60 months after transplantation. In addition, we retrospectively compared the outcome of transplanted patients to an age- and sex-matched group of severe SSc patients selected from our historical cohort and treated with conventional therapies.

**Methods:** Clinical, instrumental and laboratory data of all SSc patients who underwent AH SCT between 2003 and 2020 in our center and with a regular follow-up of 60 months after transplant, have been retrospectively analyzed. AH SCT was performed by mobilization with CTX, CD34+ cell and conditioning regimen with CTX and rabbit ATG. Survival, skin involvement assessed by modified Rodnan skin score (mRSS), cardiac and lung involvement assessed by echocardiography and lung functional parameters, and EUSTAR disease activity (EDA) scores were recorded. All transplanted patients had a rapidly progressive cutaneous disease characterized by a mRSS>14 and were unresponsive to conventional immunosuppressive therapies. Similar evaluations were made in the control group represented by age- and sex-comparable patients suffering from an equally comparable disease-duration and clinical characteristics in term of skin involvement and disease activity, and treated with conventional therapies. For this group, the enrolment period was 1991-2020.

**Results:** 35 patients underwent AH SCT, 30 females and 5 males. Patients were eligible for AH SCT when they had mRSS=14 and an EDA score=2, in the absence of severe organ involvement (renal clearance<40mL/min, DLCO<40%, ejection fraction<45%). At the baseline mean, mRSS = 21.4 ± 5, mean FVC 90.1% ± 17.9 and mean DLCO 66.5% ± 15. We observed a sustained improvement in skin thickening and a persistent reduction of EDA scores, with p-values<0.0001 for both parameters at any follow up time. Transplant-related mortality occurred in 2 patients, one at +65 days from interstitial pneumonia and one at +2 days from myocarditis (5.7%). Three patients died during the follow up from disease progression complications, one at +3 years due to fatal cardiac arrhythmia and two due to progressive lung failure at +5 years and +7 years. In the control group (68 patients), 25 patients received 6 monthly pulses of intravenous cyclophosphamide (750mg/m2), 10 received mycophenolate, 10 methotrexate, 12 rituximab, and 11 received steroids and vascular therapies, in the absence of real immunosuppressive therapies. AH SCT patients experienced a better overall survival compared with control patients (p=0.001). AH SCT was also more effective than other therapies for the outcomes of skin score (p=0.0001), lung function (p=0.0004) and disease activity (p<0.0001).

**Conclusion:** The results of this large historical cohort study of patients with severe SSc confirm efficacy of AH SCT in terms of survival, response to treatment and disease progression complications. The improvement of skin thickening and stabilization of organ function up to 5 years after transplantation, result in a global clinical improvement, as showed by the persistent reduction in the activity score. Probably as a consequence of an accurate patient selection, transplant related mortality results to be acceptable and similar to that reported in previous studies. Despite the limitation of a retrospective study, AH SCT is more effective than conventional therapies, including the latest immunosuppressive agents.

**POST1315**

**MYOCOPHANATE USE AND SYSTEMIC SCLEROSIS-ASSOCIATED ESOPHAGEAL DISEASE**

**Keywords:** Gastrointestinal tract, Disease-modifying drugs (DMARDs), Systemic sclerosis

**Correspondence:** E. Olumuyide1, H. Verma1, D. Qian1, S. Lutgen2, K. Cavaliere3, C. Dobrowolski1.

**Objectives:** To investigate the potential relationship of MMF with SSc-associated esophageal disease.

**Methods:** A retrospective chart review was completed for patients with SSc at the Mount Sinai Hospital between January 1, 2000 – January 6, 2022. Individuals with Ssc were identified using a validated ICD-10 M34 code. Data gathered included demographic factors, history of MMF use and cumulative dosage, GERD/EsD diagnosis, medication use, and other relevant clinical factors. Esophageal disease was considered to be present if a patient had any of the following: a formal diagnosis of GERD, absent/ineffective contractility on manometry, or Barrett’s esophagus identified on endoscopy. Descriptive statistics were conducted, and X² tests/t-tests were computed to compare demographic and outcome variables between patients taking MMF and those not. Multivariable logistic regression analysis was conducted to identify the relationship between MMF use and GERD/EsD prevalence.

**Results:** 612 participants were included in the study, 167 (27.3%) patients were prescribed MMF, with an average dose of 28.1g/kg. 141 (84.4%) of the patients prescribed MMF were diagnosed with esophageal disease, compared to 293 (65.9%) patients who were not prescribed MMF (p<0.01). Patients taking MMF were more likely to use a PPI (p<0.01). No differences were found in vascular risk factors (i.e. smoking, coronary artery disease, stroke, hypertension diabetes), head and neck or GI malignancy (thyroid, tongue, gastric, etc.) or presence of psychiatric comorbidities. Multivariable logistic regression revealed that total cumulative MMF dosage (OR=2.99, 95% CI=1.76-5.08, p<0.0001) was significantly associated with increased likelihood of esophageal disease.

**Conclusion:** This study revealed that patients with SSc who were prescribed MMF were more likely to have GERD/EsD, and that total cumulative dose of MMF was significantly associated with an increased likelihood of esophageal disease. There are many potential explanations for this result, including possible MMF side effects and bias by indication (i.e. patients taking MMF may have more severe disease to warrant such therapy). Additional studies (notably prospective trials) are needed to examine other possible disease modifying treatments for SSc-associated GERD/EsD.

Keywords: Gastrointestinal tract, Systemic sclerosis

1Rambam Medical Center, Hematology, Haifa, Israel; 2Bnai Zion Medical Center, Scleroderma, Haifa, Israel.

Background: Gastric antral vascular ectasia (GAVE) is a known vascular gastrointestinal (GI) complication of systemic sclerosis (SSc), characterized by a distinctive endoscopic appearance of a "watermelon stomach" [1]. In patients screened for autologous hematopoietic stem cell transplantation (AH SCT) in the "Scleroderma: Cyclophosphamide or Transplantation" (SCOT) trial, the reported prevalence was up to 22%, and even higher, 45%, specifically in patients with RNA polymerase III antibodies [2]. GAVE carries significant morbidity due to frequent and recurrent GI bleeding, requiring blood transfusions and repeated endoscopic interventions with Argon plasma coagulation (APC). There is no well-established specific therapy for GAVE in the literature. AH SCT is grade A therapy for early diffuse progressive SSc, the population at risk for GAVE. During the conditioning period, thrombocytopenia may result in bleeding from active GAVE. In the SCOT trial, patients with active GAVE were excluded from the study [2]. The data regarding the safety and efficacy of AH SCT in SSc patients with GAVE is scarce.

Objectives: To evaluate the safety and efficacy of AH SCT in SSc patients with GAVE.

Methods: We selected from our cohort of twenty adult dcSSc patients who underwent AH SCT; patients who had GAVE according to gastroscopy prior to AH SCT. We recorded the number of APC procedures before AH SCT. The complications during AH SCT: the nadir thrombocytopenia level, the need for blood transfusions and treatment-related mortality at 100 days. We report endoscopic and clinical results 12 months following AH SCT.

Results: Five dcSSc patients (mean age 49.2 ± 9.0 years, 4 [80%] females, 4 patients [80%] with RNA polymerase III antibodies and one [20%] with SCL-70 antibodies) were diagnosed endoscopically and histologically with GAVE 1-4 months prior to AH SCT. Two of them needed APC. The mean Hb level at baseline was 9.6±2.5 g/dl. At the AH SCT, three patients received conditioning with Cyclophosphamide 200mg/kg and 7.5 mg/Kg ATG, and two patients received "cardiac-safe" conditioning with rituximab 1000 mg, cyclophosphamide 60 mg/kg and fludarabine 120 mg/m². The mean nadir thrombocyte level was 41.2 × 10⁹/L (±39.1 × 10⁹/L). The mean duration of thrombocytopenia below 50 × 10⁹/L was 4.6±4.8 days. The mean number of blood transfusions during hospitalization for AH SCT was 4.4 ± 4.0 units. Only one GI bleeding episode (melena) was noted in one patient during the transplantation. Treatment-related mortality was 0%.

At the repeated upper gastrointestinal endoscopy following AH SCT (mean time after AH SCT 78 ± 4.4 months, range 4-12 months), all five patients (100%) had a complete resolution of the endoscopic as well as the histological findings of GAVE (Figure 1). The Hb level at the time of the second gastroscopy increased from baseline by 1.7 ± 1.8 g/dl, range 0-4.1 g/dl.

Conclusion: We describe the complete resolution of GAVE 12 months after AH SCT in five consecutive patients without treatment-related mortality.

incontinence, bowel movements such as diarrhea or constipation, social activities, emotional well-being) into 3 subgroups: “none to mild”, “moderate”, “severe to very severe”. GIT involvement and its severity have been compared with clinical-demographic and laboratory features.

**Results:** Study population consisted of 87 patients (M/F 7/80), median age [IQR] of 64 [54;70] years. 81(93%) cases presented GIT disorders where GERD symptoms showed the highest prevalence followed by the B/D ones. The descriptive analysis of the main characteristics is summarized in Table 1. The “UCLA SCTC GIT 2.0” questionnaire revealed a median Total score [IQR] of 0.41 [0.21;0.84]. Median score and trend of each item are reported in Figure 1. The median D/B score 1 was the statistically highest among all the other reported GIT scores (p=0.0030; p=<0.0001; p=<0.0001 respectively). The analysis of the collected data showed a positive association between GERD and D/B (r=0.4144; p=0.0001), while positive correlations were found for both total score and GERD with smoking habit (r = 0.2735; p= 0.0117; p= 0.0490) and with PPI therapy (r = 0.2270; p= 0.0345) respectively. Diarrhea was positively associated with PPI treatment (r = 0.2765; p= 0.0095), while Total score (r = -0.2181; p= 0.0424), GERD (r = -0.2327; p= 0.0301), and diarrhea (r=0.2386; p= 0.0261) were negatively associated with vascular therapy. D/B score was positively associated with the limited form of the disease (r = -0.2158; p=0.0447) but negatively with mRSS > 7(r=-0.3067; p=0.0039) and disease duration (r=-0.2602; p=0.0149). We didn’t find any correlation between GIT involvement and specific autoantibody presence.

**Conclusion:** Although the results of the present study confirm the higher prevalence of GERD in SSC, they also highlight the highest median score of D/B, often underestimated, whereas its negative correlation with the disease duration, rather than with the extension of the cutaneous involvement, seems to point at an early phenomenon not to be disregarded at the beginning of the patient follow-up. Of interest is to investigate the effective role of vascular therapy for GIT involvement. These findings underline that timely diagnosis and early treatment could provide the opportunity to implement clinical action as well as improvement in the GIT prognosis in SSC, encouraging wider and longer studies.

**Keywords:** Systemic sclerosis, Organ damage, Autoantibodies

**Methods:**

This was a single-center retrospective study of a SSc cohort followed over a 10-year period in our rheumatology department. Duration of disease progression, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets, were evaluated in all patients.

Results: 270 SSc patients were selected, from which we identified a final population of 28 (10%) anti-Ro-positive patients. The anti-SSA/Ro group included more women (26/28) with a mean age of 47.3 ± 13.7 years, most of them with diffuse subset (16/28). The presence of anti-SSA/Ro antibodies was positively correlated with presence of anti-Scl 70 antibodies (p=0.012), elevated modified Rodnan score (p=0.041), myositis (p=0.013), and lower DLCO (p=0.019). Moreover, associations were strongest for elevated CRP levels (p=0.001) and calcium cuts (p=0.001). Compared to non-anti-SSA/Ro patients, both groups were similar regarding demographic data, age at diagnosis, disease duration and type of skin involvement. As expected, the anti-SSA/Ro group had significantly more frequent erosive synovitis (p=0.002), myopathy (p=0.010), gastrointestinal involvement and interstitial lung disease (ILD) (p=0.001). No statistically significant differences were found regarding frequencies of Raynaud’s phenomenon, pulmonary hypertension, renal, vascular and cardiac involvement, nor neoplasia. There was a greater proportion of digital ulcers and calcinosis in the anti-SSA/Ro group (42% vs 17% and 58% vs 42%) without statistical significance. Again, anti-Ro antibodies seem to characterize a distinct group of SSc patients who are almost exclusively female, express elevated CRP levels, have a high prevalence of ILD, myositis, joint involvement and calcinosis, and commonly receive immunosuppressants.

**Keywords:** Organ damage, Systemic sclerosis, Outcome measures

**Background:**

In systemic sclerosis (SSc), a specific nailfold videocapillaroscopy (NVC) pattern is observed in 90% of cases and seems to be associated with severity and progression of the disease. Data about SSc patients with normal/nonspecific NVC are scarce [1].

**Objectives:**

This study aims to investigate the clinical and immunologic characteristics of SSc patients with normal or nonspecific NVC and to compare them to those with a sclerodermia NVC pattern.

**Methods:**

This was a single-center retrospective study which enrolled 270 SSc patients referred for NVC since January 2000, in our rheumatology department. Demographic and clinical features, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets and survival were evaluated.

**Results:**

270 SSc patients were selected in the database, from which we identified a final population of 19 (7%) patients with normal/nonspecific NVC pattern. The group comprised 14 females and 5 males, with a mean age of 52.7 (±17.4) years, most of them with diffuse subset (12/19). Among the cases, 8 (42%) had normal NVC and 11 (58%) had nonspecific NVC changes, characterized by isolated ramified capillaries in 42%, curved capillary limbs in 33%, giant capillaries in 16% and focal microhemorrhages in 9% of patients. The mean Raynaud phenomenon’s (RP) duration was longer (18.4 ± 14.4 years) compared to the other cases (10.2 ± 1.5 years). The difference was not significant (p=0.107). Significantly higher percentages of cases had lower overall frequency of digital ulcers (28% vs 51%, p=0.04). Presence of synovitis (p=0.010) and myositis (p<0.001) was positively correlated with normal/nonspecific NVC changes. Regarding other organ involvement, the cases also had less severe pulmonary involvement, less frequent digestive involvement and/or pulmonary arterial hypertension than controls, but these differences did not reach significance. No differences in mortality were found between the groups.

**Conclusion:**

SSc patients with normal/nonspecific NVC changes have less organ involvement and less overall disease severity than those with a typical SSc specific NVC pattern, with no between-group differences. Musculoskeletal involvement was the only factor independently associated with normal/nonspecific NVC. It is possible that SSc with normal NVC may be at lower risk of progression to severe visceral and skin involvements, but prospective studies are required.

LOW CD32 EXPRESSION ACCOUNTS FOR THE ASSOCIATION OF CD21LOW B CELLS WITH DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

E. Kourkouni1, A. Mavropoulos2, S. Tsiochos3, T. Simopoulou4, C. Katsiaris5, D. Bogdanos6,1, L. Sakkas2,1

1Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece. 2Rheumatology and Clinical Immunology, Larissa, Greece; 3Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece, Department of Rheumatology and Clinical Immunology, Larissa, Greece; 4Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece; 5Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece; 6Rheumatology and Clinical Immunology, Larissa, Greece.

Background: Abberations of B cells have been implicated in the pathogenesis of systemic sclerosis (SSc) [1] and CD21low B cells, which express high levels of activation markers, have recently been associated with vascular manifestations in SSc [2]. CD32 (FcγRII), comprised of three isoforms A, B, and C, is involved in B cell regulation and antibody production. B cells do not express FcγRIIA and mainly express the inhibitory FcγRIIB isoform [3].

Methods: Thirty patients, 23 women (median age 56 years. Interquartile range 32–81) and 7 men (median age 60 years, Interquartile range 52–79) fulfilling the ACR/EULAR 2013 criteria for SSc were included in the study. Peripheral blood mononuclear cells from patients were analyzed with multicolor flow cytometry using anti-CD19 monoclonal antibody (moAb), anti-CD21 moAb, and anti-CD32 moAb, that recognizes both the FcγRIIA and FcγRIIB isoforms.

Results: The percentage of CD21low B cells was significantly increased in patients with DUs compared to patients without DUs (difference between means: 24.6, 95% CI 5.37–43.8, p = 0.014). The percentage of CD21low/CD32low B cells were significantly increased in patients with DUs compared to patients without DUs (difference between means: 23.24 ± 7.364, 95% CI 8.152–38.32, p = 0.0036) (Figure 1A). The percentage of CD21high/CD32high B cells was significantly decreased in the DUs group (difference between means: -26.61 ± 9.312, 95% CI -45.69 to -7.539, p = 0.0080) (Figure 1B).

Conclusion: Our study suggests that low expression of CD32 accounts for the association of CD21low B cells with DUs in SSc and implies that CD32 may have an inhibitory effect on CD21low B cells.

POS1323 BODY COMPOSITION IN PATIENTS WITH SYSTEMIC SCLEROSIS: RESULTS OF A COMPUTED TOMOGRAPHY STUDY

Keywords: Imaging, Systemic sclerosis

M. Binda1, G. Ficheri2, B. Moccali3, L. Pilati2, A. Doria2, C. Giraudo2, E. Zanatta1, 1Padova University Hospital, Department of Medicine - DIMED, Division of Rheumatology, Padova, Italy; 2Padova University Hospital, Department of Medicine - DIMED, Division of Radiology, Padova, Italy

Background: Subclinical primary muscular involvement and malnutrition may occur in a significant percentage of patients with systemic sclerosis (SSc), and they are potential risk factors for the development of sarcopenia [1]. Sarcopenia is defined as age-associated loss of muscle mass, strength, and function, and unlike other chronic inflammatory disorders, it has been poorly investigated in SSc patients. In recent years, some imaging methods have emerged for the evaluation of sarcopenic markers such as altered muscle composition and fat infiltration (myosteatosis).

Methods: Patients affected with SSc (2013 EULAR/ACR criteria) referring to our tertiary center from 2015 to 2021 who underwent chest computed tomography to assess pulmonary involvement were included. A semi-automatic segmentation of the subcutaneous fat and paravertebral muscle was performed at the level of the 12th dorsal vertebra using a software and the following body composition variables (BCV) were collected: subcutaneous fat area, subcutaneous fat Hu, paravertebral muscle area, paravertebral muscle Hu. Myosteatosis was considered as Hu values >30. The Student’s t-test was used to evaluate if any difference between the BCV occurred between males and females. Logistic regression analysis was applied to assess the role of the BCV on the overall survival while the Spearman correlation coefficient was used to evaluate the relationship between the BCV and the skin score. For all the analyses the applied significance level was p<0.05.

Results: Sixty SSc patients were included (51 females; mean age 55.63±14 years). Most patients were positive for anti-nuclear antibodies (ANA, 90%), with anti-topoisomerase I specificity in 61.6% of them; twenty-nine patients (48.3%) were affected by the diffuse cutaneous form. At baseline, the mean modified Rodman skin score (mRSS) was 10.22 (±8.8) and the mean revised EUSTAR activity index was 2.08 (±1.4). Signs of myosteatosis were detected in forty-seven (78.3%) SSc patients. Males showed significantly greater muscle areas (males 9732±3019 vs. females 6599±1328 mm²; p<0.001) and less hypodense subcutaneous fat (males 76±18 vs. females 88±16 Hu; p=0.027). Overall, seven patients (11.7%) were deceased at a 5-year follow-up. No correlation was found between BCV and the mRSS. None of the radiological variables emerged as a predictor of survival.

Conclusion: Most patients with SSc are affected by myosteatosis, even those without symptoms of muscle involvement, while overall body composition does not appear to predict survival. The results of our pilot study may open the door to evaluating the role of body composition in SSc patients/larger cohorts, as travel burden looking at different time-points in the disease course may provide further insights.

TREATMENT WITH NINTEDANIB IN SYSTEMIC SCLEROSIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE: SAFETY AND EFFECTIVENESS AFTER ONE YEAR IN A REAL-LIFE COHORT

Keywords: Safety, Systemic sclerosis, Lungs

J. Corada1, A. Guilen-Del-Castillo1, I. Blazquez1, C. Codina1, A. Anton1, J. Mestre1, A. Gil2, J. Perurena-Prieto3, I. Ojarguren4, A. Villar3, C. P. Simeon4.

1Vall d’Hebron University Hospital, Internal Medicine Department. 2Scleroderma Autoimmune Disease Unit, Barcelona, Spain. 3Vall d’Hebron University Hospital, Immunology Department, Barcelona, Spain. 4Vall d’Hebron University Hospital, Pneumology Department, Barcelona, Spain

Background: Interstitial Lung Disease (ILD) is detected in 80% of the high resolution CT scans (HRCT) of patients with Systemic Sclerosis (SSc). ILD is responsible for 60% of the mortality related to SSc. Although classic treatment is based on immunosuppressant therapies, nintedanib has recently been approved for SSc-ILD as disease modifying antibiotic drug.

Objectives: To describe the safety and effectiveness of nintedanib over one year follow-up in a cohort of SSc-ILD patients.

Methods: Basal characteristics of SSc patients, concomitant therapy, adverse events, and pulmonary function test after one year of nintedanib treatment were collected in a cohort with SSc-ILD from a tertiary hospital. SPSS 20.0 was used for descriptive statistics.

Results: Twenty-two patients were treated with nintedanib for SSc-ILD. 17 (77.3%) of the patients were women, with a median (interquartile range, IQR) age at ILD diagnosis of 45.7 (39.4 – 56.8) years, and with a median extent of ILD features in the HRCT at the beginning of the treatment of 29.7% (20.0% - 39.9%). The median period from the ILD diagnosis to nintedanib initiation was 46.5 months. As concomitant therapies, 17 out of 22 (81.4%) patients were under some medication –severe infections were described only in 3 cases-, taking into account that among them 14 (62.4%) patients were under concomitant immunosuppressant treatment. Nine (40.9%) patients suffered from diarrhea, and 5 (22.7%) presented elevation of liver enzymes, which required dose reduction in 2 (9.1%), temporary interruption of nintedanib in another 2 (9.1%), and permanent withdrawal in 1 (4.5%) patient. During a median period of follow-up of 29.5 months, 3 (13.6%) patients died, 13 (59.1%) required a nintedanib dose reduction, 4 (18.2%) temporary interruption, and 5 (22.7%) a permanent withdrawal. The absolute forced vital capacity (FVC) percentage after the first 12-month follow-up increased in 0.15 % (–3.8 – 5.5), which meant a relative increase in FVC of 2.3% (–4.7 – 7.9).

Conclusion: Nintedanib treatment for SSc-ILD showed a satisfactory safety profile, constituting diarrhea and elevated liver enzymes the most common adverse events related with the drug. An increase in infection rates cannot be established as the majority of the patients were under concomitant immunosuppressant therapies. FVC was stable during follow-up, which supports the effectiveness of nintedanib for SSc-ILD in real-life cohorts.

**Rheumatology Department, Roma, Italy.**

**Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Rheumatology Department, Leeds, United Kingdom**

**Background:** Treatment of Systemic Sclerosis (SSc) remains challenging and some clinical studies reported the efficacy of Rituximab (RTX) in skin disease and in stabilizing lung involvement. Recently 2 randomized clinical trial demonstrated the efficacy of RTX in SSc and in lung involvement in connective tissue diseases (1,2), however current data are limited by the small number of samples examined and the short duration of follow-up.

**Objectives:** We aimed at retrospectively evaluate the efficacy, safety, and long-term persistence of RTX therapy in a monocentric SSc cohort.

**Methods:** All clinical records of SSc patients (pts) treated with RTX in our center were retrospectively analyzed. Demographic, clinical and disease characteristics, treatment approach, combination therapies, and adverse events during RTX treatment were considered. Every 6 months, skin score, pulmonary function test and swollen joint count (SJC) modifications as well as digital ulcer occurrence were recorded.

**Results:** Fifty-two SSc pts (pts) have been treated with RTX in our center since 2005. The mean age of the pts was 53.3±24.3 years and 21.5% were male. The disease duration at the time of the first treatment with RTX was 4.4±2.8 years and the mean reached follow-up was 6.2±2.2 years (range 2-17 years). Forty pts (77%) had a diffuse cutaneous involvement, 33 pts (63.6%) had anti-topoisomerase positivity, 45 (86.2%) an interstitial lung disease on high resolution chest CT, 30 pts (59.2%) arthritis or tenosynovitis, and finally 38 pts (73.1%) presented any history of digital ulcers. Twenty-five (48.1%) pts had been previously treated with cyclophosphamide. During RTX treatment, 39 pts (75.0%) received an immunosuppressive combination therapy, most with mycophenolate mofetil (53.8%). Concomitant glucocorticoids treatment was assumed by the 53.8% of pts. Twenty-five pts (46.1%) were treated with Rituximab for only one clinical involvement, 27 pts (51.9%) received treatment for more than one organ involvement including skin, lung or joint. Overall, 82.7% were treated for progression of skin disease, 50.0% for lung involvement deterioration and 23.1% for active arthritis. Treatment showed improvement in the skin score, arthritis, and/or stabilization of the pulmonary functional status in 44 pts (84.6%), while in the remaining 8 pts, therapy was stopped because of worsening of the disease over the 6 months of follow-up. Among responders, skin score improved from 173±8.9 to 10.3±8.6 (p=0.04), while the FVC and DLco remained stable (87.4±5.5% to 86.2±20.5% and 68.3±23.9% to 64.3±22.1%, respectively). As expected, there was an improvement in DAS28 (4.9±0.8 to 19.0±0.5, p<0.01). Finally, there was a reduction in the rate of ulcer occurrence (46.15% to 21.70%, p=0.04). Twenty-two pts (42.3%) were treated with one single cycle of therapy (1 yr two weeks apart), while the remaining 30 pts were treated with repeated cycles of RTX, with a mean number of cycles of 4.3±2.0. Among the re-treated pts, 50% were treated every year and 50.0% at the time of new clinical worsening, and retreatment was done every 60.5±31.4 months. All pts re-treated with RTX on demand responded to the therapy. Nineteen percent of pts developed adverse events (5.7% leukopenia, 7.7% infusion reactions, 1.9% sepsis, 3.8% pneumonia). Ten pts (19.2%) died during follow-up: 8 deaths were related to organ complication of SSc and 2 to cancer.

**Conclusion:** Our data suggest long-term efficacy and safety of RTX in pts SSc. Further real world studies will be necessary to evaluate the best therapeutic approach with RTX (regular cycles or retreatment when clinical worsening occurs) and/or the combination with other immunosuppressant drugs.

DIFFERENTIATING "SCLERODERMA" WITH "NON-SCLERODERMA" PATTERNS IN NAILFOLD CAPILLARY MICROSCOPY USING A DEEP LEARNING MODEL

Keys: Systemic sclerosis

V. Korendovych1, P. Kornsten1, 1University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany

Background: Nailfold capillary microscopy is used for diagnostic purposes in rheumatology since many years. Abnormal nailfold capillaries are also listed in the 2013 ACR/EULAR classification criteria for systemic sclerosis (SSc) [1]. A fast-track algorithm to differentiate between “sclerodermia” and “non-sclerodermia” patterns of capillary microscopy was published in 2019, and is being applied in clinical routine as a useful decision algorithm [2]. Artificial intelligence is increasingly implemented in many spheres of everyday life, including medicine. Keras is a publicly available deep learning framework, which is widely used for research purposes, in particular for constructing artificial neural networks [3].

Objectives: To estimate the ability of a deep learning model, to differentiate between sclerodermia and non-sclerodermia capillary microscopy patterns.

Methods: Capillary microscopy was performed using Optilia Digital Capillaroscope. We analyzed capillary microscopy images, which were equally subdivided into two groups, including sclerodermia and non-sclerodermia patterns. Subsequently the pictures were assigned to training, validation and test sets. Each set contained the same number of images with sclerodermia- and non-sclerodermia patterns. Then we trained a deep learning model using training and validation datasets to differentiate between the aforementioned capillaroscopy patterns. A test set was applied to estimate the model performance in an independent data set. The technical side of the study was performed using a 2D convolutional neural network, which was constructed based on Keras deep learning libraries (example Picture 1).

Results: A total of 1076 capillaroscopy images from 70 patients were analyzed: 780, 196 and 100 pictures in the training, validation and test sets accordingly. Each image dataset contained an equal amount of pictures from sclerodermia- and non-sclerodermia patterns. The trained model showed an accuracy of 87.8% with sensitivity of 94.9% (95% CI 0.905 to 0.99), specificity of 80.6% (95% CI 0.73 to 0.88) and an area under the curve (AUC) of 0.9326 in the validation set. In the test set, there was a slightly better model performance with an accuracy of 92%, a sensitivity of 96% (95% CI 0.91 to 1), a specificity of 88% (95% CI 0.79 to 0.97) and an AUC of 0.9742.

Conclusion: Despite the relatively small image dataset, the developed deep learning model could successfully discriminate sclerodermia- vs. non-sclerodermia capillaroscopy patterns, which may be applied in an automated assessment of capillaroscopy pictures in the future.

Alcohol-related interstitial lung disease – a rare but under-recognized clinical entity

Figure 1. LUS concordance with FVC was quite good (86.8% and 86.9%, respectively) and quite low (9.2% and 15.3%, respectively) for the number of B-lines (BL) and FVC. The concordance for Leicester cough questionnaire and St.George respiratory questionnaire was very low (15.5% and 12.5%, respectively).

Conclusions: We performed LUS for the follow-up of SSc-ILD patients treated with NINT. Changes in PLI and BL were not significantly correlated with the functional and subjective trend of the patients. PLI variations showed a greater concordance for Leicester cough questionnaire and St.George respiratory questionnaire (69.2% and 43.5%, respectively) than BL variations (35.7% and 28.5%, respectively).

POS1330 DEVELOPMENT AND VALIDATION OF A CLINICAL SCORE FOR MORTALITY PREDICTION IN SYSTEMIC SCLEROSIS: THE SSCORE STUDY

Keywords: Prognostic factors, Systemic sclerosis, Systematic review

L. Dullius1, A. Ribeiro3, M. Spier Borges2, M. Gubert2, M. Loporchio2, V. Lelisoz2, A. Azeredo-da-Silva2, V. Hax1, M. Bredemeier1, R. Chaki1

1Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil; 2Federal University of Rio Grande do Sul, School of Medicine, Porto Alegre, Brazil; 3Department of Rheumatology, Hospital de Clínicas de Porto Alegre, Brazil.
Background: Systemic sclerosis (SSc) is one of the most lethal systemic autoimmune diseases. Considering recent advances in drug therapy and safety concerns, predicting mortality may contribute to a personalized treatment decision [1,2].

Objectives: Our goal was to develop and validate a clinical score for mortality prediction in SSc patients (SScore).

Methods: For SScore development, a systematic literature review (SLR) in PubMed and EMBASE (up to July 2022) was performed by two independent reviewers and hazard ratios (HR) from clinically relevant and statistically significant 5-year SSc mortality predictors were meta-analyzed. Considering heterogeneity (I2 test) and publication bias (Egger's test and funnel plots), we selected the most representative HR of each predictor. The weighted risk of death was estimated by Poisson's regression model, and the final SScore was the sum of each predictor score, varying from 0 to 1. For SScore validation, 91 SSc patients (ACR-EULAR 2013 or LeRoy and Medsger classification criteria) were consecutively included in a prospective cohort and followed-up between 2019 and 2022 in the outpatient clinics of two tertiary hospitals. Death was confirmed by medical records and phone calls.

Results: Out of 6,893 studies (2,539 in PubMed; 4,354 in EMBASE), 33 were included in the meta-analysis [3,449 deaths in 15,403 SSc patients over 8.6 years (mortality 22.4%)]. Six predictors were included in SScore: age, dyspnea, malignancy, renal impairment, anti-Scl70 and sclerodema renal crisis (Table 1). In the validation cohort, there were 13 deaths (mortality 14.3%) among the 91 SSc patients over 2.6 years [age 60.5 (±10.3) years-old; women 92.3%; 81.2% white; SSc duration 13.0 (±8.1) years; diffuse cutaneous SSc 22.0%]. The best SScore cut-off was 0.18 (sensitivity 61.5%, specificity 87.2%, positive and negative predictive values 44.4% and 93.2%, respectively, and accuracy 79.1%). The area under the receiver operating characteristic curve (Figure 1) was 0.78 (95%CI 0.64-0.92). SScore was higher among those who died (p<0.001).

NYHA (New York Heart Association) functional classes III and IV: dyspnea, palpitation or exhaustion with mild physical activity/rest; renal impairment: creatinine elevation/proteinuria.

Conclusion: An accessible score for SSc mortality prediction (SScore) was developed from a SLR and validated in a real-life scenario with high specificity and negative predictive value and acceptable accuracy. Larger cohort studies are needed to clarify SScore usefulness in clinical practice, including treatment individualization.

ANTI-NUCLEAR VALOSIN-CONTAINING PROTEIN-LIKE AUTOANTIBODIES ARE ASSOCIATED WITH A NEW CLINICAL PHENOTYPE IN SYSTEMIC SCLEROSIS PATIENTS: LIMITED CUTANEOUS SUBSET WITH RECURRENT CALCINOSIS AND HIGHER RISK OF CANCER

Keywords: Systemic sclerosis, Autoantibodies, Malignancy

J. Perurena-Prieto1,2,3, L. Viñas-Giménez2, M. T. Sanz-Martínez2, A. Selva-O’callaghan4, E. L. Callejas-Moraga5, R. Colobran1,2,3, A. Guillen-De-Castillo1, C. P. Simeon Aznar4, V. d’Hebron University Hospital (HUVH), Immunology Division, Barcelona, Spain; 1Vall d’Hebron Research Institute (VHIR), Translational Immunology Group, Barcelona, Spain; 2Autonomous University of Barcelona (UAB), Department of Cell Biology, Physiology and Immunology, Bellaterra, Spain; 3Vall d’Hebron University Hospital (HUVH), Systemic Autoimmune Diseases Department, Internal Medicine Department, Barcelona, Spain; 4Vall d’Hebron University Hospital (HUVH), Department of Clinical and Molecular Genetics, Barcelona, Spain

Background: It has been reported that 80-85% of established systemic sclerosis (SSc) patients present anti-nuclear autoantibodies (ANAs) [1]. However, in a group of clinically heterogeneous patients with high-titer ANAs no SSc-specific autoantibodies are found. It is likely that these patients present autoantibodies that have not been previously described. Protein immunoprecipitation (IP) followed by mass spectrometry (MS) has the potential to identify these new autoantibodies.

Objectives: To identify novel autoantibodies through a new protein IP assay based on bioorthogonal non-canonical amino acid tagging (BONCAT) combined with MS and to describe the clinical associations of these novel autoantibodies.

Methods: Sera samples and clinical data of 307 SSc patients from Vall d’Hebron University Hospital were collected. All patients met the LeRoy and Medsger criteria and 84.0% fulfilled the 2013 ACR/EULAR classification criteria of SSc. ANAs were tested in all patients by indirect immunofluorescence (IF) on HEP-2 cells and positive reactions were categorized according to the International Consensus on ANA Patterns (ICAP) classification. Specific autoantibodies (anti-Scl70, -centromere, -RNA-polymerase III, -fibritalin, -NOR-90, -Th/To, -PM/Scl, -Ku, -U1-RNP, -U11/U12-RNP) were evaluated by a commercial immunoblot and chemiluminescence immunosassay and traditional RNA IP. Patients negative for all tested autoantibodies (n=25) were further studied by IP assay based on BONCAT. Protein IP was performed by incubation of sera of these patients with protein A-sepharose beads in IP buffer, and subsequent incubation with labelled K562 cell extracts. Obtained immunoprecipitates were fractionated by 10% SDS-polyacrylamide gel electrophoresis (SDS-PAGE). Protein bands detected on SDS-PAGE were further analysed by Liquid Chromatography-MS.

Results: Five patients tested by protein IP showed a band with a molecular weight of 110-115kDa on SDS-PAGE and a homogeneous nuclearular pattern (AC-8) by IIF. These bands were identified as nuclear valosin-containing protein-like (NVL) by MS. All anti-NVL positive patients fulfilled the 2013 ACR/EULAR classification criteria of SSc and presented the limited cutaneous (lCSSc) subtype. Anti-NVL positive patients were characterised by higher age at SSc onset (51.7 vs. 39.9 years, p=0.041) and higher prevalence of calcinosis (100% vs 10.9%, p<0.001). More importantly, anti-NVL positive patients presented higher risk for malignancy (60.0% vs 4.3%, p=0.005; OR 33.0; 95% CI 3.4-323.4) and synchronous cancer (40.0% vs 2.2%, p=0.023; OR 30.0; 95% CI 2.1-433.1).

Conclusion: We have identified NVL as a novel autoantibody target on SSc patients by a new protein IP assay. Anti-NVL positive patients presented a lCSSc phenotype characterized by high prevalence of calcinosis and higher risk of cancer, including synchronous cancer. Further work is required to confirm the clinical associations that were found in this cohort of SSc patients and to evaluate the presence of anti-NVL in other autoimmune diseases and conditions.

ASSOCIATION BETWEEN SYSTEMIC SCLEROSIS AND CANCER: A NATIONWIDE COHORT STUDY

Keywords: Systemic sclerosis, Epidemiology, Malignancy

Y. Eun1, K. D. Han2, J. K. Ahn1, J. Kangbuk Samsung Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2 Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)

Background: Previous studies have shown an association between systemic sclerosis and cancer. However, because the disease is rare, large-scale studies are lacking, especially in Asians.

Objectives: We aimed to compare the incidence of cancer in patients with SSC and age- and sex-matched controls in a nationwide population-based cohort in Korea.

Methods: We included patients with SSC defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1.5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were incidence of cancer. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of cancer between patients with SSC and controls.

Results: A total of 5,145 patients with systemic sclerosis and 25,725 controls were included in the study. During the study period, the overall cancer incidence rate was 11.07 per 1,000 person-years in patients with systemic sclerosis and 7.59 per 1,000 person-years in controls. Overall cancer risk was 1.5 times higher in patients with systemic sclerosis (adjusted hazard ratio 1.46, 95% confidence interval 1.28–1.87). Lung cancer and lymphoma had a high risk in both male and female patients with systemic sclerosis, and cological cancer had a high risk only in male patients with systemic sclerosis. The risk of biliary cancer, skin cancer, and cervical cancer was high in female systemic sclerosis patients.

Conclusion: This nationwide cohort study showed that patients with systemic sclerosis were associated with increased cancer risk. Clinicians should be aware of cancers that may increase the risk in patients with systemic sclerosis and apply appropriate screening measures.

WORK PARTICIPATION AND WORK DISABILITY IN BELGIAN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

J. Desimpel1, A. S. De Craemer1,2, L. Deimez1, D. Elewaut1,2, P. Carron1,2, F. Van den Bosch1,2, V. Smith1,2,3, Ghent University, Internal Medicine and Pediatrics, Faculty of Medicine and Health Sciences, Ghent, Belgium; 2 Ghent University Hospital, Rheumatology, Ghent, Belgium; 3 VIB-UGent, Center for Inflammation Research, Ghent, Belgium

Background: Systemic sclerosis (SSc) is an immune-mediated connective tissue disease that potentially affects multiple organ systems. Besides health-related complications, patients often describe work-related difficulties (e.g. productivity loss, sick leave, work disability) that may result in a major individual burden and the rise of indirect costs for society.

Objectives: Despite the rheumatology community’s growing interest, work participation and its influencing factors is still an underestimated and underexplored field of research in SSc patients. This study therefore aims to provide up-to-date data about work status and its determinants in SSc patients.

Methods: Adult SSc patients were questioned on their socio-economic status at the occasion of an outpatient visit at the rheumatology clinic of Ghent University Hospital, a tertiary hospital in the Flemish region (February 2020 to March 2021). All patients were included in a SSc clinical care path (Belgian Systemic Sclerosis Cohort) and fulfilled the LeRoy and Medsger’s classification criteria. Employment rate was compared with general Flemish population after adjustment for age and sex. Comparative data on the average duration of working life in Belgium were derived from Eurostat (reference year 2020).

Results: Among the 108 participants, 81 (75%) belonged to the working age category (18-65 y/o). The crude employment rate in SSc patients of working-age was 64%, resulting in a standardized employment ratio of 0.90 (95%CI 0.69–1.17). About half of these patients worked full time (53%), with a mean±SD of 41.7±8.7 weekly working hours. The median duration of labor force participation in SSc patients was 40.0 years, while the average career duration in the Belgian population amounted 33.4 years. Long term work disability was reported as the most common reason for leaving the labor market (20%). Patients on work disability were significantly older, less highly educated, more functionally disabled and reported a lower quality of life than patients having a paid job. Job characteristics did not differ significantly between patients with and without a paid job (Table 1).

Conclusion: Our data refute the common perception that SSc patients show a significantly lower work participation grade compared to the general population. Socio-demographic but not job-related characteristics are associated with work disability in this population. Quality of life is remarkably better in patients who perform a paid job, reinforcing the importance to support active labor force participation.

ASSOCIATION BETWEEN LIPID PROFILE AND RISK OF INCIDENT SYSTEMIC SCLEROSIS: A NATIONWIDE POPULATION-BASED STUDY

Keywords: Epidemiology, Systemic sclerosis, Real-world evidence

O. C. Kwon1, K. D. Han2, M. C. Park1, 1 Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2 Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)

Background: Lipid metabolism is altered in patients with systemic sclerosis (SSc), mediating activation of immune cells and fibroblasts. However, it is unclear whether altered lipid profile in individuals without SSc is associated with a risk of future development of SSc.
Objectives: To assess the association between lipid profile and future development of SSc.

Methods: Individuals without SSc who underwent national health check-ups in 2009 were selected and followed up through 2019 from a nationwide database of the Korean National Health Insurance Service. Serum levels of total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and triglyceride, measured on the date of health check-up in 2009, were each categorized into quartiles (Q1 [lowest], Q2, Q3, and Q4 [highest]). Individuals who developed SSc during follow-up were identified. Cox regression analyses adjusted for multiple covariates were performed to estimate the adjusted hazard ratios (aHRs), and 95% confidence intervals (CIs) according to the quartiles of levels of TC, HDL-C, LDL-C, and triglyceride, respectively, using Q1 as the reference.

Results: Of the 9,894,996 individuals selected, 1,355 individuals developed SSc during a mean follow-up of 9.2 years, accounting for an incidence rate of 1.49 per 100,000 person-years. Compared with Q1 levels, Q4 levels of TC (aHR 0.91, 95% CI 0.892–0.930), HDL-C (aHR 0.80, 95% CI 0.778–0.828), and LDL-C (aHR 0.85, 95% CI 0.826–0.881) were associated with a lower risk of incident SSc, while Q4 levels of triglyceride (aHR 1.060, 95% CI 0.953–1.292) were not. Higher quartiles of TC (p for trend<0.001), HDL-C (p for trend<0.001), and LDL-C (p for trend<0.001) were associated with a larger effect size.

Conclusion: Serum levels of TC, HDL-C, and LDL-C were inversely associated with the risk of incident SSc. Our findings provide new insights that altered lipid profile could be considered a risk factor for incident SSc.

Background: In Systemic Sclerosis, beyond the value of Nailfold capillaroscopy, there is still a deep unmet need in quantitative imaging surrogate outcome measures to assess activity and/or severity of peripheral vascular disease. This has been halting the implementation of trials targeting vascular disease beyond crude endpoints such as number of digital ulcers (DU). Quantitative MRI based scores have boosted the implementation of new trials in inflammatory arthritis.

Objectives: To determine the value of MRI-based Digital Artery Volume Index (DAVIX©) score in predicting the burden of DU disease as well as other vascular endpoints including clinical manifestation and patient reported outcome scores (PROs).

Methods: Consecutive patients with Raynaud’s phenomenon were enrolled in two independent randomized discovery and validation cohorts. Data collected included electronic medical information, patient function tests, nailfold capillaroscopy, modified Rodnan Skin Score (mRSS), history/presence of DU (defined as DU Disease), sHAQ-DI, Cochin hand function and Borg scales. Discovery cohort had clinical follow up data at 12 months, Validation cohort had only baseline data. DAVIX© (dominant hand) was calculated by MRI time of flight based, digital artery volumetric assessment over the volume of each finger, as %mean of the 4 fingers [1, 2]. Mann-Whitney test was used to compare DAVIX© between patients subgroups. Correlations between DU disease in both hands and clinical endpoints/PROs were performed using Pearson’s and Spearman’s tests, as appropriate. Data analysis was conducted using R software.

Results: 233 patients were recruited in discovery (D=91) and baseline validation (V=142) cohorts. 139 patients fulfilled 2013 SSc classification criteria (62 in discovery cohort and 77 in validation cohort), 94 were patients with VEDOSS (2013 ACR/ESR/EULAR SSc classification criteria) and not included in further analysis. Median (IQR) disease duration was 5.9 (7.0) and 4.7 (6.0) years in the two cohorts (P=0.618). DAVIX© was significantly lower in patients with DU disease in both cohorts (0.34% and 0.49% vs 0.65% and 0.75%) compared to patients with no DU (D: P=0.0018; V: P=0.003). DAVIX© correlated with baseline DLCO% in both cohorts (r=0.368 and 0.315, P=0.004 and 0.038, respectively). There was no correlation with mRSS or FVC% whereas, DAVIX© correlated with FVC/DLCO ratio (r=-0.337, P=0.009). The analysis of PROs showed that DAVIX© correlated best with VAS DU (r=-0.291 and -0.243, P=0.05 for both cohorts) and VAS Raynaud (r=-0.270, P=0.048 for the discovery cohort), whereas there was no significant correlation with the other PROs. Importantly, DAVIX© correlated inversely with disease duration in both cohorts (r=-0.415 and -0.441, P<0.001 for both). In the discovery cohort, 12 patients developed new (7) or their first (5) DUs during follow-up and their mean DAVIX© was 0.23% vs 0.66% of 73 patients who did not develop any new DUs (P=0.02). Standard Receiver Operating Curve indicated that DAVIX©<0.36% conferred a 4 times higher risk of new DU s, independently of any other clinical variable.

Conclusion: DAVIX© is a feasible, automated, contrast-free imaging outcome measure that reflects worse vascular disease as far as DU disease, DLOC%, and patient reported burden of Raynaud’s and DU disease. DAVIX© validation in Randomized Controlled Trials would offer a novel imaging based surrogate outcome measure of vascular disease in Systemic Sclerosis.

Pain in rheumatic diseases, including fibromyalgia

LONG-TERM OPIOID USE AMONG PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: IMPACT OF VARYING DEFINITIONS

Keywords: Pain, Fibromyalgia, Inflammatory arthritides

J Y T Huang1, D Jenkins2, B Birile Yimer1, C Ramirez Medina1, N Peek3,4, M Lunt, W Dixon4, M Jani1,4. 1University of Manchester; Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom; 3University of Manchester, NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester, United Kingdom; 4Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: People living with rheumatic and musculoskeletal diseases (RMD) are frequently prescribed opioids for non-cancer pain. A proportion of RMD patients newly prescribed an opioid will transition to long-term opioid use, and represent a high-risk subgroup for opioid dependence, abuse and harms. However, definitions of long-term opioid use in the literature vary considerably, making it difficult to characterise the scale of the issue and design future interventions to address it [1,2].

Objectives: 1) To evaluate the proportion of patients transitioning to long-term opioid use in new users across 6 RMD conditions using varying definitions used in the literature 2) To assess the proportion of long-term opioid users who transition to opioid dependence.

Methods: Patients aged ≥18 years with a diagnosis of rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), systemic lupus erythematosus (SLE), osteoarthritis (OA) and fibromyalgia and without prior cancer, with a new episode of opioid use between 01/01/2006 and 31/10/2021 and at least a 5-year follow-up in the Clinical Practice Research Datalink (CPRD) were included. CPRD is a database of anonymised UK primary care electronic health records representative of the national population. Long-term opioid users were defined using 3 different definitions: 1) Standard (most commonly used); ≥3 opioid prescriptions issued within a 90-day period, or ≥90 days opioid supply in the first year of follow-up (excluding the first 30 days). 2) Stringent: ≥10 opioid prescriptions filled over ≥90 days, or ≥120-day opioid supply in the first-year follow-up. 3) Broad: ≥3 monthly prescriptions (no need to be consecutive) in the first 12 months. Opioid dependence was defined as RMD patients who had relevant Read Codes within 5 years after a new episode of opioid use. The proportions of long-term opioid use and opioid dependence for RMDs were calculated.

Results: This study included 841,047 patients of whom 12,260 had a code for RA, 5,195 PsA, 3,046 AxSpA, 3,081 SLE, 796,276 OA, and 21,189 fibromyalgia. The highest proportion of long-term opioid users among the 6 RMDs was patients with fibromyalgia (27.4% for Standard; 20.9% for Stringent, and 33.7% for Broad), followed by RA (25.7%, 18.5%, and 32.3% respectively) and AxSpA (23.8%, 17.3%, and 29.6% respectively) (Figure 1-Stacked bar chart). On average, using Broad definition showed 10-13% higher than Stringent definition for all RMDs. As the Venn diagram in Figure 1, 241,727 patients met any of the definitions of long-term use, of which half fulfilled all 3 definitions. The Broad definition was able to identify additional half of long-term users, with 24.0% overlapping with the Standard definition. In total, 685 (0.06%) RMD patients were diagnosed with opioid dependence within 5 years after starting opioids. Similar proportions of opioid dependence were observed in long-term opioid users across all definitions: 332 (0.18%) for Standard, 281 (0.23%) for Stringent, and 355 (0.15%) for Broad definitions. Moreover, 323 out of 685 RMD patients (47.2%) who had a diagnosis of opioid dependence were not classified as long-term opioid users by the 3 definitions.

Conclusion: Around 1 in 3 fibromyalgia patients and 1 in 4 RA AxSpA patients fulfilled definitions for long-term opioid use within 12 months after starting opioid. The low prevalence of opioid dependence across all RMDs, defined using Read Codes alone is likely to be considerably underrepresented in clinical practice. This reflects both coding practices in primary care and under recognition of the scale of the problem in patients who are those on long-term opioids.

PHARMAKON OR THE ART THAT HEALS: TRANS-DISCIPLINARY ARTISTIC-TRANSFORMATIVE WORKSHOPS FOR FIBROMYALGIA SYNDROME

Keywords: Non-pharmacological interventions, Patient reported outcomes, Fibromyalgia

C Villani1; M Sapio2; VE Giorgi3; P Sarzi-Puttini3, 1Transdisciplinary Designer of Artistic-cultural Experiences, Freelance, Palemò (PA), Italy; 2Ospedale Buccheri La Ferla FBF; Pain Medicine, Palemò, PA, Italy; 3IRCCS Istituto Galeazzi - Sant’Ambrogio, Milan State University School of Medicine, Rheumatology Department, Milan, Italy

Background: Fibromyalgia syndrome (FMS) is a widespread chronic pain syndrome with many associated symptoms. It is frequently related to a traumatic event (1), strong and of short duration, or slight but protracted over time. A multidisciplinary therapeutic approach is recommended by international guidelines. The transformative experience (TE) allows for a profound and immediate change that differs from linear and gradual psychological change; this helps create novel responses to the same initial thoughts and actions, thereby breaking the maladaptive emotional/behavioral loop elicited by chronic stress and trauma (2), creating a sort of “virtuous” cycle, adaptive rather than maladaptive and long-lasting. In this study, TE was specifically elicited through transformative art (TA), an intrinsically transdisciplinary tool, in different ways in the three arms of the study.

Objectives: Validation of the efficacy (in terms of quality of life and sleep, self-esteem, self-efficacy) of transdisciplinary TA workshops in patients with FMS.

Methods: Prospective observational study lasting 8 months (February-October, 2021), in which the effectiveness of three different TA workshops in patients with FMS was evaluated: in group 1 participants were encouraged to review their autobiographies and illness in a humorous sense; in group 2 participants were guided to express their own realities of chronically ill patients in poetry; group 3 was based on the guided narration of works of art according to visual thinking strategies integrated with the principles of narrative medicine. Patients were divided into the three laboratories according to their preference. Tests were administered at baseline and post-workshop. The activities took place entirely online.

Results: 109 FM patients completed the study (n=3 males, mean age 52.9 mean years from diagnosis 11 [SD 8.6], No differences were found among the three groups at baseline in terms of clinimetric variables. Data analysis made by a Wilcoxon non-parametric test (WNPT) of the three groups in conjunction showed a statistically significant improvement of the Pittsburgh Sleep Quality Index (PSQI) (p<0.05), Response to Stressful Experiences Scale (RSES) (p<0.05), World Health Organization–Five Well-Being Index (WHO-5) (p<0.001) and Global Health scale (GH) (p<0.05). No significant difference was found for The Mindful Attention Awareness Scale (MAAS) (p=0.2663). A WPNT was performed to compare baseline and final results of the three groups separately. The best performance was seen in Group 1, since patients ameliorated in almost all parameters: PSQI (p<0.05), GH (p<0.05), SAP dimension 1 (p<0.05), 2 (p<0.05) and 4 (p<0.05), WHO-5 (p=0.001), MAAS (p=0.895), RSES (p=0.0673) and SAP dimension 3 (p=0.5673) resulted nonsignificant, although very close to significance. Sleep (p<0.05) and the 3rd dimension of SAP (p=0.05) improved in patients of Group 2; whilst self-esteem (p<0.05) and WHO-5 (p<0.05) did in Group 3.

Conclusion: Our research shows that art, experienced as TA, leads to significant improvements of the psychophysical condition of FMS patients. TA can be seen as a crucial mediator for overcoming the traumatic/illness path, probably through the generation of "pivotal mental states" (PIMS), defined as a ‘hyper-plastic state aiding rapid and deep learning that can mediate psychological transformation’ [3].

Figure 1 Long-term opioid use by definitions and overlap between them
**Efficacy of Very Low-Calorie Ketogenic Diet in Obese Patients with Fibromyalgia:** Preliminary Results from a Monocentric Interventional Study

**Keywords:** Diet and nutrition, Pain, Fibromyalgia

**Background:** Obesity can worsen fibromyalgia (FM) and very low-calorie ketogenic diet (VLCKD) is a potential therapeutic option in diseases that share clinical and pathophysiological features with FM [1].

**Objectives:** In this pilot interventional study, we investigate the effects of VLCKD in obese patients with FM.

**Methods:** Adult FM patients with a BMI ≥ 30 kg/m² and who had failed standard low-calorie diets, were eligible for VLCKD. The weight-loss program was preceded by 4 weeks of free-diet (W-4 to W0). During the first period of VLCKD (W1 to W4), patients could eat protein preparations and vegetables. In the next phase (W5 to W8), natural proteins were gradually integrated in the dietary regimen. Ketosis was assessed weekly with urine strips. Carbohydrates were then progressively reintroduced (W9 to W20). Changes in BMI, FM impact questionnaire (FIQ) and Hospital Anxiety and Depression Scale (HADS-A for anxiety and HADS-D for depression) were evaluated at established timepoints. As previously reported, a change of 14% in FIQ was considered clinically relevant [2]. This interim analysis evaluates patients who reached the final visit after 20 weeks from the beginning of VLCKD (W20).

**Results:** At data cut-off, 20 patients, all females, were enrolled in the study. Two patients discontinued the intervention while 4 are currently in the maintenance phase. Mean age of the 14 patients who reached W20 was 50.4 years and BMI was 36.9. Baseline characteristics are summarized in Table 1. No significant difference in BMI, FIQ, HADS-A and HADS-D was observed from W-4 to W0. All patients lost weight during the first period of VLCKD and this achievement was maintained through W20 (Figure 1, panel A). Mean BMI decreased from 36.9 at W0 to 34.5 at W4, 33.3 at W8 and 32.2 at W20 (all p < 0.001 compared to W0). Compared to W0, a significant reduction of mean FIQ (Figure 1, panel B) from 64.3 to 35.2 was observed at the end of W4 (p < 0.001) and was maintained also at W8 (mean FIQ of 38.8; p = 0.004) and at W20 (mean FIQ of 39.1; p = 0.007). Analysing the trend in each participant, at W4, all 14 patients showed a reduction in FIQ, which was clinically relevant in 13 (93%). Compared to W0, a meaningful improvement in FIQ was still observed at W20 in 12 cases (86%). However, change in BMI was not significantly correlated with change in FIQ at any time-point. HADS-A and HADS-D improved significantly from W0 to W4, W8 and W20. (Figure 1, panels C, D). Mild constipation was reported by 8 patients (57%), fatigue by 4 (29%) and headache by 3 (21%). No major safety concern emerged.

**Conclusion:** These are the first data on the efficacy of VLCKD in FM. All patients achieved improvement in disease activity outcomes during the ketogenic phase, which was maintained also after carbohydrate reintroduction. Our data suggest that ketosis might exert beneficial effects in FM which extend beyond the promotion of rapid weight loss.

**References:**

Objective: To evaluate the prevalence of sexual dysfunction in a large cohort of FM female patients, using a validated questionnaire.

Methods: The cohort was composed of 373 FM female patients, median age 49.1 years. Qualisex questionnaire was used to evaluate sexual dysfunction in patients with fibromyalgia. Qualisex questionnaire was validated with Cronbach’s alpha test (0.878), median value 5.3. Women with lower grade of education (p=0.002), married (p=0.001) and with lower sexual feeling with partner (p=0.001) showed higher values of Qualisex. Menopause status, drug absorption and comorbidity did not influence patients’ sexual quality. High values of HADS-A and HADS-D showed a positive correlation with Qualisex Total (p=0.001; r=0.312; p=0.001; r=0.542 respectively) as well as high values of VAS pain, VAS fatigue and VAS dryness (p<0.001 r=0.438; p<0.001 r=0.375; p<0.001 r=0.70 respectively). Relationship duration also presented a positive correlation (p=0.001; r=0.202). Multivariate analysis observed a significantly influence of relationship duration, VAS pain, fatigue and dryness, HADS-A/D, R-FIQ and all relation (p<0.001 r=0.202).

Results: Multivariate analysis of the Qualisex questionnaire represents a good test to evaluate sexual disorders in FM women. Different aspects contribute to sexual dysfunction both from a psychological (anxiety, depression, loss of self-esteem, decreased sexual attraction) and a physical (pain, fatigue, etc.) point of view with an important impact of FM on sexual life and consequently a worsening of FM symptoms. Over a demotivation feeling, inability to live a “normal everyday life”, the reduced sexual function contributes to a bad quality of life. Other studies are needed to analyze a demotivation feeling, inability to live a “normal everyday life”, the reduced sexual function contributes to a bad quality of life. Other studies are needed to analyze.

Conclusion: Sexual dysfunction in FM patients is significant and it seems reasonable to conclude that the assessment of disease impact should be diversified, taking gender differences into account. It could improve the sexual aspect in the global contest of FM and to investigate this important aspect in FM male patients.

1. Bazzoli L, Giacomelli C, D. Franculli F, Giardina D, Iannuccelli C, Gattamelata A, Conti F, Di Franco M, Di Franco M. Sapienza University, Division of Rheumatology, Department of Clinical Internal, Anesthesiologic and Cardiovascular Sciences, Rome, Italy; "UniCamillus, Saint Camillus International University of Health Science, Rome, Italy"

Background: FM is a chronic syndrome clinically characterized by widespread musculoskeletal pain associated with symptoms like fatigue, sleep disturbances and cognitive impairment. Prevalence is higher in females but the 2010/2011 and 2016 revisions of the American College of Rheumatologist (ACR) criteria reduced prevalence differences and the actual female:male ratio is approximately 3:1. Even if in the last years some studies have been conducted regarding gender differences in FM, disease severity is still assessed using questionnaires, such as the Revised Fibromyalgia Impact Questionnaire (FIQR), designed for female patients and validated through a predominantly female sample.

Objectives: Of this pilot study was to compare the 21 items of the FIQR and female patients in order to evaluate the possible existence of a gender bias.

Methods: In this case control study, all the consecutive patients with a diagnosis of FM (2016 ACR criteria) referring to our out-patients Fibromyalgia Clinic between May 2020 and December 2022 were asked to answer an online survey, including demographic characteristics, disease variables and the Italian version of the FIQR. Among the 544 patients that compiled the questionnaire, 78 patients, 39 males and 39 females matched for age and disease duration, were consecutively enrolled in order to compare their total FIQR score and the different domains scores.

Results: The univariate analysis of the FIQR scores, taking account of the total score and of the different domains of FIQR, showed that total scores and physical function domain scores were significantly higher in females compared to males. No significant differences emerged between the two groups compared to males. The results of our pilot study showed that female patients obtain significantly higher scores in the FIQR total score and in the physical function domain score.

Conclusion: These preliminary results indicate that the use of the FIQR as a severity index in male patients probably underestimate the disease impact in this group. In order to confirm these results the sample needs to be increased but it seems reasonable to conclude that the assessment of disease impact should be diversified, taking gender differences into account.

Cognitive dysfunction is a frequent condition in patients with AS. We established a negative correlation between cognitive status and the evening BDNF level - with an increase in evening BDNF level cognitive dysfunction deepens (P < 0.05).

Conclusion: Cognitive dysfunction is a frequent condition in patients with AS. Our study results demonstrate circadian rhythm of BDNF production during the day and relationship between BDNF production and cognitive status – cognitive dysfunction in AS patients is associated with high evening BDNF levels.

COGNITIVE DYSFUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RELATIONSHIP WITH BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF)

Keywords: Cognitive function, Spondyloarthritides, Fibromyalgia

I. Shapoval1, H. Vyshar1, L. Peresbiuk1, V. Kromenko1, L. Shvets1, M. Stanislavchuk1, 1National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Chair of Internal Medicine #1, Vinnytsya, Ukraine

Background: Normal cognitive status is essential for daily activities, but many people with chronic autoimmune rheumatic diseases are impaired in this function. This is probably related to the age of the patients, the education level, the duration of the disease, the disease activity. Pronounced pain syndrome in ankylosing spondylitis (AS) patients is a risk factor of cognitive dysfunction [1, 2]. There are also literature data regarding the involvement neurotrophins, namely brain-derived neurotrophic factor (BDNF), in the mechanisms of pain regulation and psychoemotional disorders [3].

Objectives: Our study aimed to evaluate the cognitive status in patients with AS and the relationship with BDNF.

Methods: We examined 143 patients (81.8% male) with AS according to modified New York criteria. The mean age of the examined patients was 42.1±11.3 years. The Mini Mental State Examination MMSE (Folstein M.F. et al., 1975) was used to assess the psychological and cognitive status. The level of BDNF in plasma was determined twice a day (at 8:00 and 20:00) by the ELISA method, also we calculated the ratio between morning and evening BDNF level (BDNF index ‘8:00/20:00’). The study was conducted in compliance with bioethical standards. All data were analyzed using IBM Statistics SPSS 23 software.

Results: Cognitive dysfunction, according to MMSE, was diagnosed in 90 (62.9%) AS patients. The values of the MMSE scale in AS patients ranged from 10-second pause. Patients received 2000 stimuli per day (50 stimuli in 40 seconds of stimulation (frequency of 10 Hz, for a total of 50 stimuli) and a intensity of 130% of the predetermined motor threshold over the left dorsolateral prefrontal cortex (DLPFC). One session of rTMS consisted of 5 seconds of stimulation (frequency of 10 Hz, for a total of 50 stimuli) and a 10-second pause. Patients received 2000 stimuli per day (50 stimuli in 40 repeated sessions). The placebo was applied with an inactive “sham” coil which resembles active treatment. The intensity of symptoms was assessed with Tender Point Examination (TPE), Visual Analog Scale of Pain (VAS), Brief Pain Inventory (BPI), Beck Depression Inventory II (BDI II), Beck Anxiety Inventory (BAI), Montreal Cognitive Assessment (MoCa), Medical Outcome Studies Sleep Scale (MOS SS), Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F), 36-item Short Form Survey (SF-36), and Revised Fibromyalgia Impact Questionnaire (FIQ).

Results: There was no difference between groups in any of the characteristics at baseline. There was a decrease in BDI score after the treatment period, but the change was more prominent in the rTMS group compared to the placebo (p=0.064). rTMS was also superior in a decrease in FIQIR score (p=0.054) (Table 2.) and an increase in vitality through SF-36 (p=0.003). Moreover, placebo treatment led to a significant reduction in sleep disturbances (p=0.035). There were no differences between groups in delta values before and after treatment regarding the rest of investigated characteristics (Table 1, p=0.05).

Conclusion: Preliminary results suggest a reduction in the impact of the disease and depression, as well as an increase in the vitality of participants who have been treated with rTMS. The placebo effect on a reduction of sleep disturbances can be partly explained by the stimulating effect of rTMS. Because this was an interim analysis, the presented results should be taken with caution.

POS1343
INFLUENCE OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION OF CNS ON FIBROMYALGIA PATIENTS - A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY (INTERIM ANALYSIS)

Keywords: Patient reported outcomes, Fibromyalgia, Non-pharmacological interventions

Z. Velickovic1, S. Radovanovic2,3, G. Radunovic1,1, Institute of Rheumatology, Internal Medicine - Rheumatology, Belgrade, Serbia;3Institute for Medical Research, Neuroscience, Belgrade, Serbia; University of Belgrade, School of Medicine, Belgrade, Serbia

Background: Fibromyalgia syndrome (FMS) is a chronic disorder characterized by diffuse pain, sensitivity to sensory stimuli, fatigue, cognitive impairment, mood and sleep disorder. The side effects of drugs used in treatment (i.e. antiplateptics) can mimic certain symptoms of fibromyalgia (i.e. impaired balance, dizziness), so there is a huge need for alternative treatment. Repetitive transcranial magnetic stimulation (rTMS) is a non-invasive therapy utilizing a magnetic field to stimulate different brain structures. rTMS is registered as adjuvant therapy for major depressive disorder, migraine, and obsessive-compulsive disorder, and its efficacy is being investigated for other conditions.

Objectives: The main aim was to evaluate the influence of rTMS in alleviating the symptoms in patients with fibromyalgia.

Methods: Sixteen patients were randomized to rTMS (n=10) or sham treatment (n=6). rTMS was applied in 10-day sessions with a frequency of 10 Hz and an intensity of 130% of the predetermined motor threshold over the left dorsolateral prefrontal cortex (DLPFC). One session of rTMS consisted of 5 seconds of stimulation (frequency of 10 Hz, for a total of 50 stimuli) and a 10-second pause. Patients received 2000 stimuli per day (50 stimuli in 40 repeated sessions). The placebo was applied with an inactive “sham” coil which resembles active treatment. The intensity of symptoms was assessed with Tender Point Examination (TPE), Visual Analog Scale of Pain (VAS), Brief Pain Inventory (BPI), Beck Depression Inventory II (BDI II), Beck Anxiety Inventory (BAI), Montreal Cognitive Assessment (MoCa), Medical Outcome Studies Sleep Scale (MOS SS), Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F), 36-item Short Form Survey (SF-36), and Revised Fibromyalgia Impact Questionnaire (FIQIR).

Results: There was no difference between groups in any of the characteristics at baseline. There was a decrease in BDI score after the treatment period, but the change was more prominent in the rTMS group compared to the placebo (p=0.064). rTMS was also superior in a decrease in FIQIR score (p=0.054) (Table 2.) and an increase in vitality through SF-36 (p=0.003). Moreover, placebo treatment led to a significant reduction in sleep disturbances (p=0.035). There were no differences between groups in delta values before and after treatment regarding the rest of investigated characteristics (Table 1, p=0.05).

Conclusion: Preliminary results suggest a reduction in the impact of the disease and depression, as well as an increase in the vitality of participants who have been treated with rTMS. The placebo effect on a reduction of sleep disturbances can be partly explained by the stimulating effect of rTMS. Because this was an interim analysis, the presented results should be taken with caution.
The features of pain in patients in remission is different from other conditions (high disease activity or fibromyalgia), suggesting different underlying biological mechanisms.

Gemelli IRCCS, Immunology Research Core Facility – Gemelli Science and Technology Park (GStEp), Rome, Italy

Background: Rheumatoid arthritis (RA) is a chronic disease characterized by a high degree of disability and pain. Remission is the optimal goal but, even when it is reached, the pain can persist as ‘residual pain’.

Objectives: The aims of the study were (i) to characterize the size and perception of residual pain and (ii) to evaluate the possible impact of residual synovitis on pain perception in remission RA patients.

Methods: One hundred twenty-seven RA patients (defined by 2010 ACR/EULAR criteria), of which 68 in clinical and ultrasound remission (REM-RA) and 29 in high disease activity (HDA-RA) defined by DAS28-CP-R were enrolled in the study. Thirty fibromyalgia patients (2016 ACR criteria) were enrolled as a control group (FIBRO). Upon enrolled, demographic, clinical and ultrasound features were collected for each patient and an assessment of pain symptom was performed for each patient according to the RAID, FACIT, GHQ and VAS-pain questionnaires. Patients with RA underwent minimally invasive ultrasound-guided biopsy of the synovial membrane of the knee in order to assess the degree of synovitis, according to the Krenn Score (KSS).

Results: Considering the RA group, the synovitis degree is directly correlated with the life quality and disability, as demonstrated by the inverse correlation between FACIT and DAS28-CP-R (R2=0.506, p<0.0001). Furthermore, considering the pain mental aspects, the total GHQ score (R2=0.407; p<0.0001) and BDI II (R2=0.407; p<0.0001) were collected for each patient and an assessment of pain symptom was performed for each patient according to the RAID, FACIT, GHQ and VAS-pain questionnaires. Patients with RA underwent minimally invasive ultrasound-guided biopsy of the synovial membrane of the knee in order to assess the degree of synovitis, according to the Krenn Score (KSS).

Results: Considering the RA group, the synovitis degree is directly correlated with the life quality and disability, as demonstrated by the inverse correlation between FACIT and DAS28-CP-R (R2=0.506, p<0.0001). Furthermore, considering the pain mental aspects, the total GHQ score (R2=0.407; p<0.0001) and BDI II (R2=0.407; p<0.0001) were collected for each patient and an assessment of pain symptom was performed for each patient according to the RAID, FACIT, GHQ and VAS-pain questionnaires. Patients with RA underwent minimally invasive ultrasound-guided biopsy of the synovial membrane of the knee in order to assess the degree of synovitis, according to the Krenn Score (KSS).

Conclusion: Remission status in RA is associated with a better psycho-physical state than in HDA patients but, despite that, there is the persistence of a certain degree of residual pain, regardless of the subclinical synovitis degree. It emerges

that the features of pain in patients in remission is different from other conditions (high disease activity or fibromyalgia), suggesting different underlying biological mechanisms.

PAIN OVER 5 YEARS IN OUR EARLY RHEUMATOID ARTHRITIS UCLouvain BRUSSELS COHORT: RESULTS AND CORRELATION WITH CLINICAL RESPONSE, QUALITY OF LIFE

Keywords: Quality of life, Rheumatoid arthritis, Patient reported outcomes

C. Deamet1, E. Sarpati1, M. Lauzur2, B. Joly2, T. Cayroy2, T. Sokolowsk1, A. Arramovska1, P. Durez1, 1Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium; 2Institute of Experimental and Clinical Research (IREC), UCLouvain, Health Sciences Division, Brussels, Belgium

Background: Pain is a major patient reported outcome in early rheumatoid patients (ERA). Pain is associated with disease activity but could be also related to non-inflammatory conditions. Chronic pain has a negative impact on quality of life in ERA patients. The main treatment objective in ERA is remission or low disease control, but relief of pain is a priority of patients.

Objectives: To evaluate the pain course and the proportion of unacceptable pain (VASp>4) during a five-years follow-up in ERA patients and to investigate correlation with clinical response and quality of life.

Methods: 474 ERA patients fulfilling the 2010 EULAR/ACR criteria included in our ERA UCLouvain Brussels cohort were retrospectively analyzed. All were naive to csDMARDs (MTX), b- or tsDMARDs with symptoms duration < 12 months. Pain was assessed using a visual analogue scale (0-100mm) and unacceptable pain was defined as a VAS pain > 40mm (VASp>4) based on the patient acceptable symptom state. VASp, HAQ and DAS28-CP-R scores were assessed at baseline (BL), 6, 12, 36 and 60 months in order to correlate the % of ERA with an unacceptable pain (VASp>4), non clinical response (DAS28-CP-R>3.2) and no restored quality of life (HAQ>0.5).

Results: Data from 474 eligible ERA patients were collected. The average age of the population is 48.5 years, and the BMI is 25.3. 70.5% of the patients are women, 27.1% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA). The evolution of VAS pain over 5 years of follow-up is shown in Figure 1:

Figure 1. At BL, the mean VAS pain at the baseline was at 60.2 +/- 26.5mm (range 0-100mm). VASp pain was reduced by 45% (mean 33.1+/- 28.5 mm) at 6 months and remained stable with 51.7% reduction (mean 29.0 +/-276mm) at 5 years.

78% of patients (n=368) reported an unacceptable pain at diagnosis which was reduced to 40.4% (n=163) at 6 months and 33% at year 5 (Figure 2):
